# Intergovernmental Panel on Climate Change 2007 Assessment:

"Warming of the  
climate system is  
unequivocal ..."

"*most of the observed increase in globally averaged temperatures since the mid-20th century is very likely due to the observed increase in anthropogenic greenhouse gas concentrations*"

# What is radiative forcing (of climate change)?

*Forcing is the perturbation of the planetary radiation budget in absence of (almost!) any other change*

# Utility of radiative forcing

$$\Delta T \approx \lambda \Delta F$$

$\Delta T$  is *global-mean surface temperature change* (K)

$\Delta F$  is *global-mean radiative forcing* ( $\text{W m}^{-2}$ )

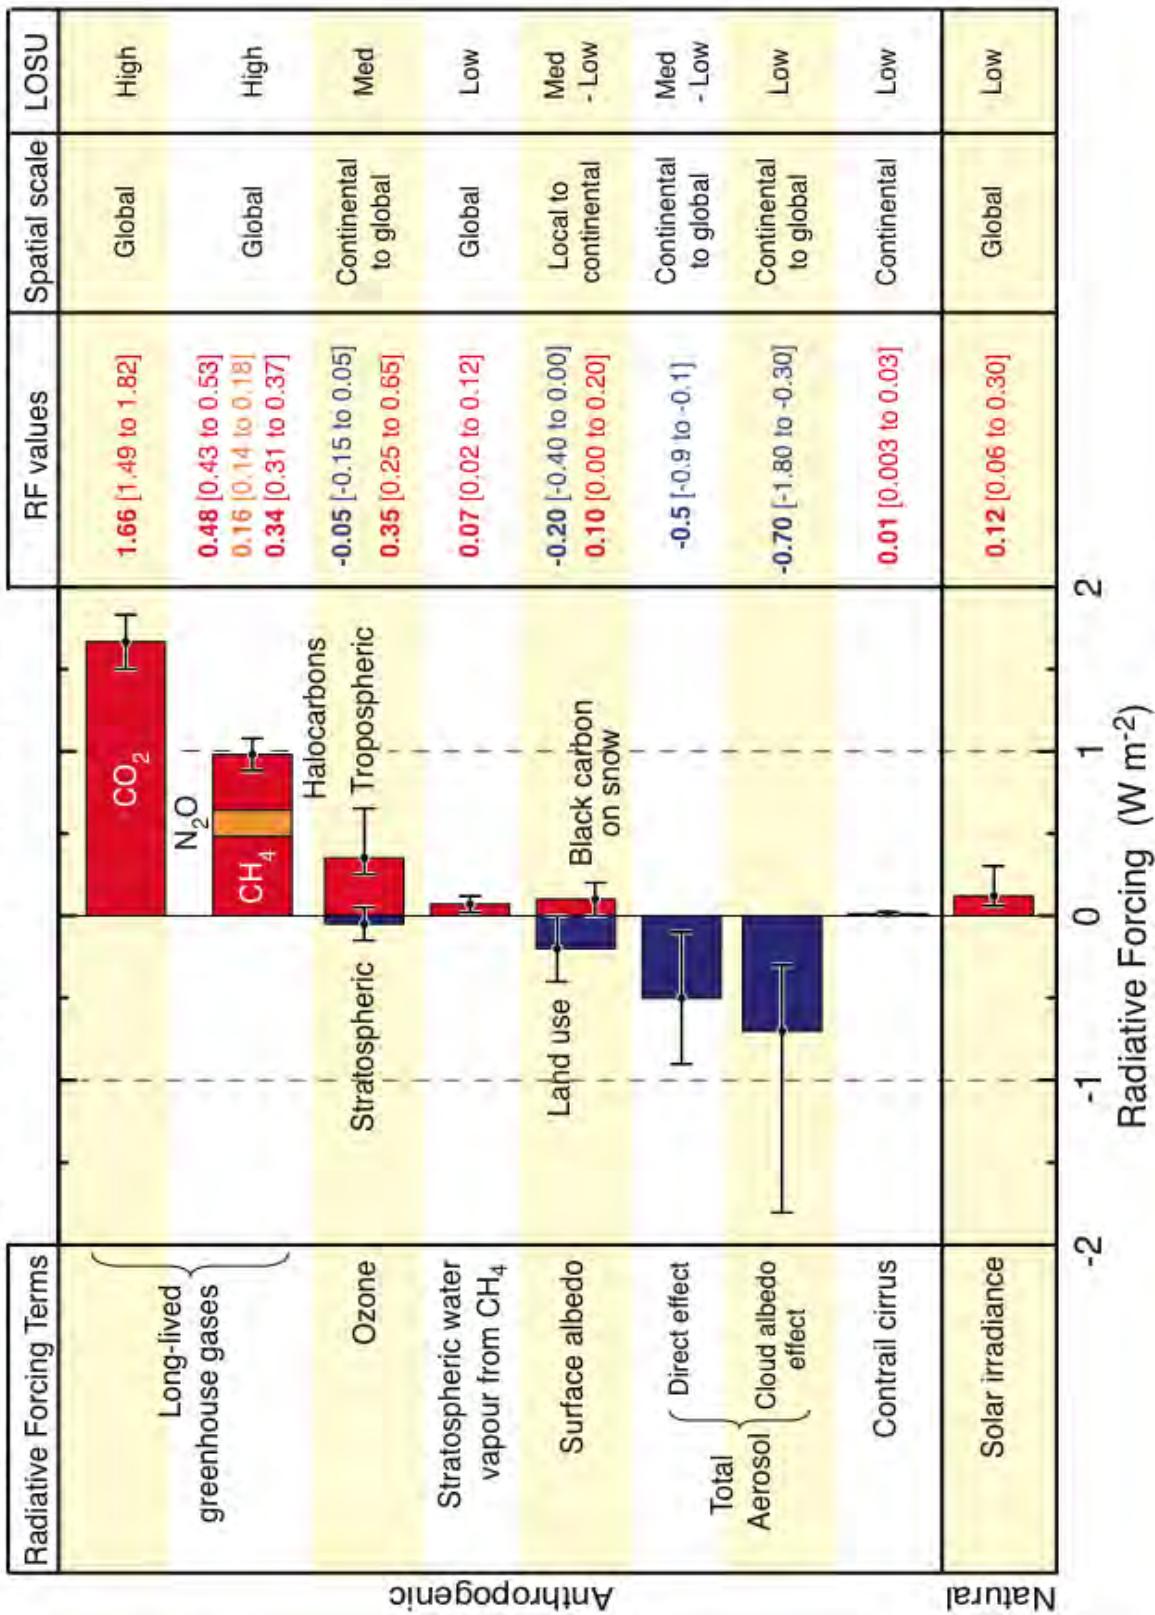

$\lambda$  is the poorly known *climate sensitivity parameter*  
( $\text{K}(\text{W m}^{-2})^{-1}$ )

Radiative forcing gives useful first order estimate of climate effect without resort to a complex climate model, and sidesteps uncertainty in climate sensitivity

©IPCC 2007: WG1-AR4

## Global Mean Radiative Forcings

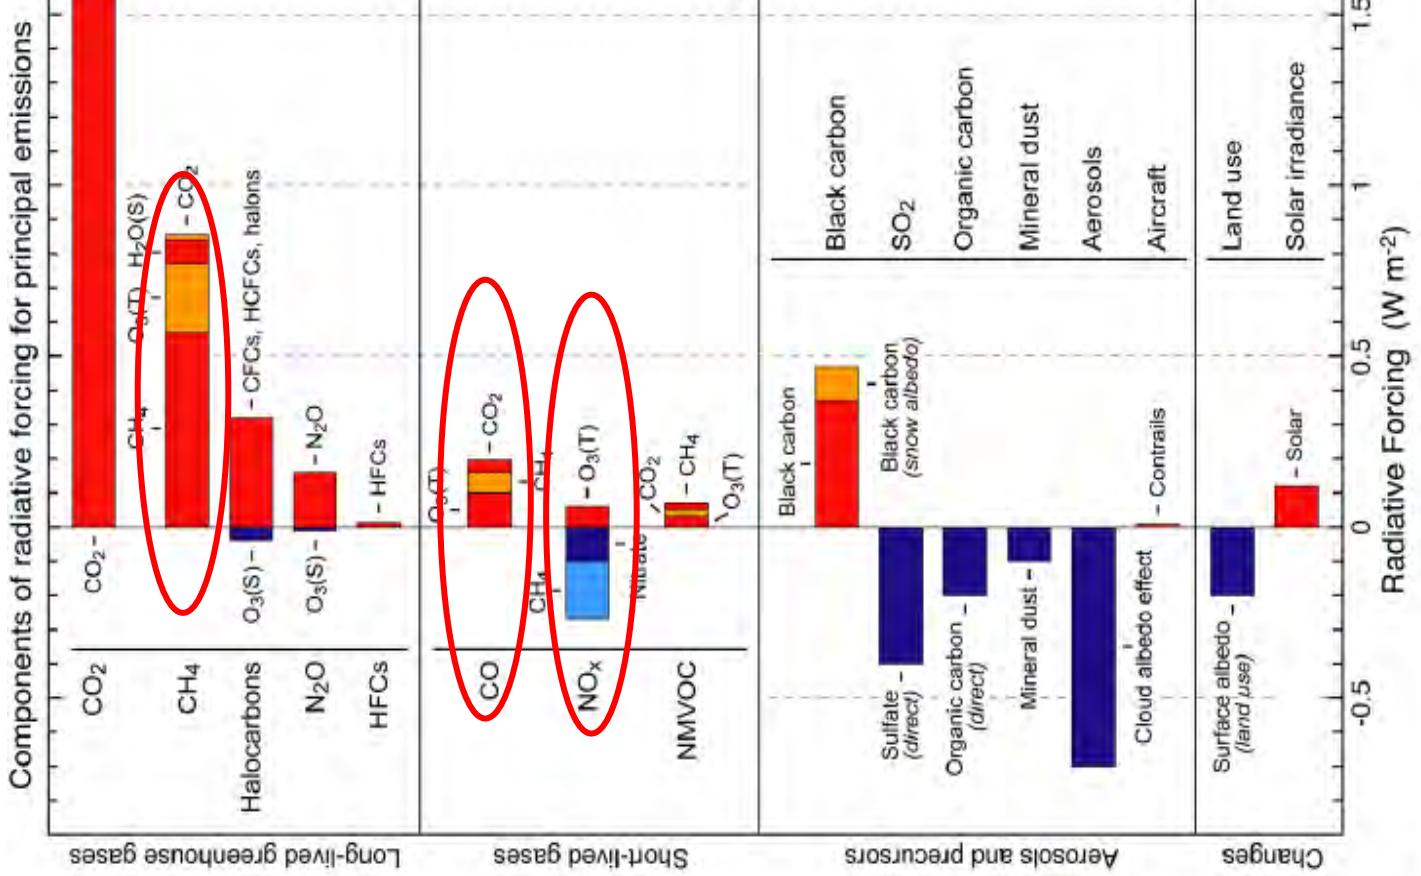

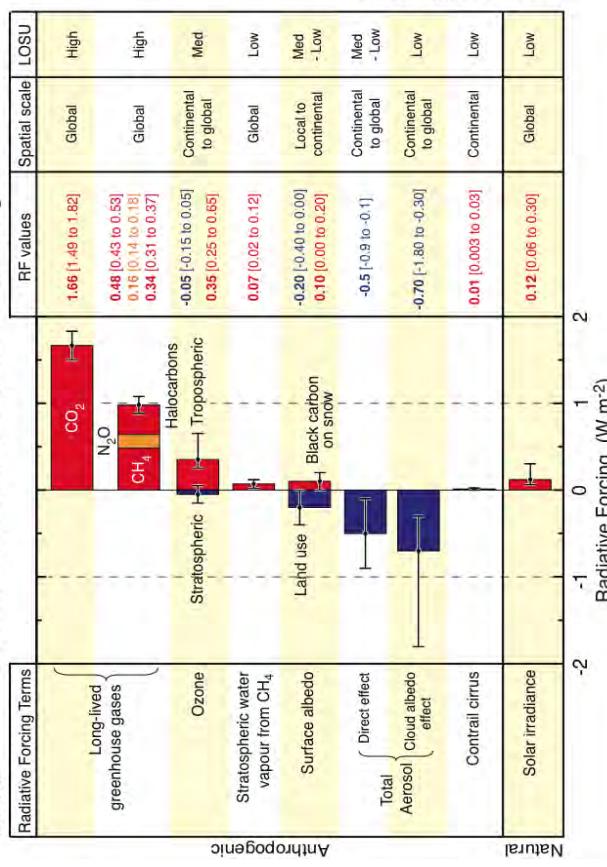

**Panel A.**

# A different view of forcing, based on emissions

## Note methane, $\text{CO}$ , $\text{NO}_x$

### Global Mean Radiative Forcings

IPCC, 2007

# Contents

- A bit of background
- Comparing the emissions – the Kyoto Way
  - Beyond Kyoto?
  - Aviation – an extreme example
  - Carbon capture and storage

# UN Framework Convention on Climate Change, 1992

- UNFCCC requires that we stabilise atmospheric concentrations "at a level that would prevent *dangerous* anthropogenic interference with the climate system"
- Comprehensive approach: "measures should cover *all relevant sources, sinks and reservoirs*" and be "*cost effective*"

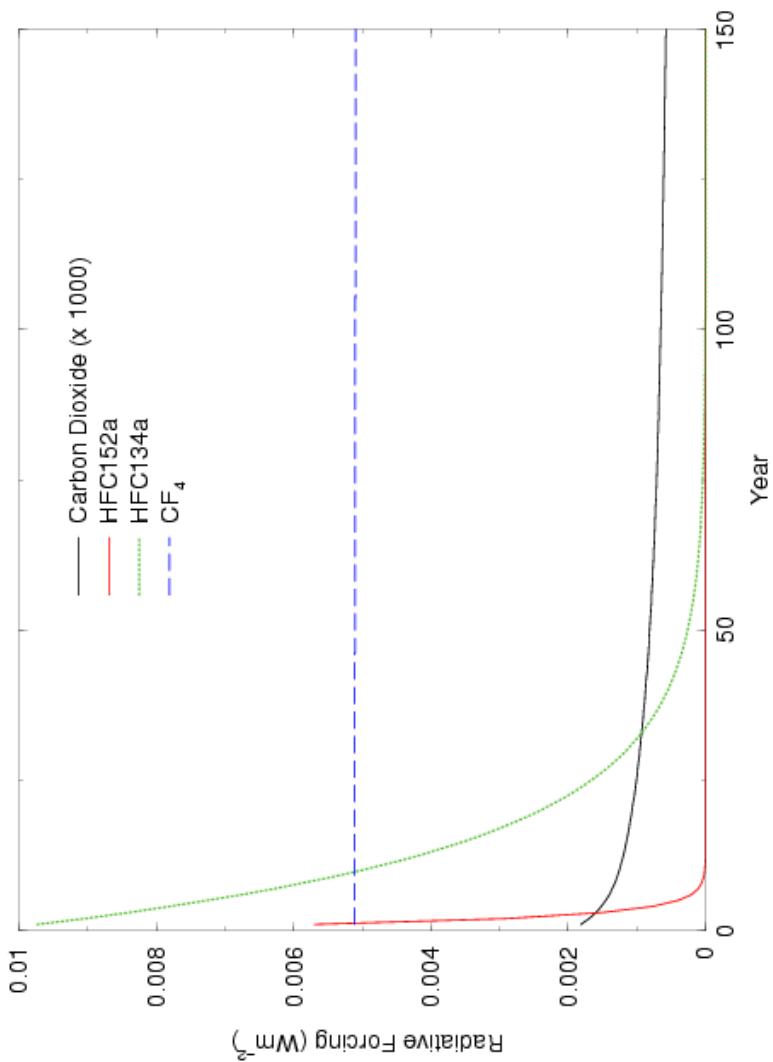

<http://unfccc.int>

# Kyoto Protocol to UNFCCC, 1997

- The Kyoto Protocol commits signatories to control emissions of a range of gases: CO<sub>2</sub>, CH<sub>4</sub>, N<sub>2</sub>O, HFCs, PFCs, SF<sub>6</sub>
- Requires method to put emissions on a common scale
- Kyoto uses the Global Warming Potential (GWP) with a 100-year time horizon. Widely accepted by the user community

# What is the GWP?

Time-integrated radiative forcing following a pulse emission of a gas, normally relative to pulse emission of  $\text{CO}_2$ .

But relative effect depends on choice of "time horizon" ... for  $\text{CH}_4$  GWP varies from 72 for 20 years, to 25 for 100 years, to 8 for 500 years.

# What kind of “equivalence” does the GWP give?

- Equivalence of emission reductions in GWP terms does not (necessarily) lead to equivalence in temperature change
- GWP is just one possible metric; it may not be the best – but what does “best” mean?

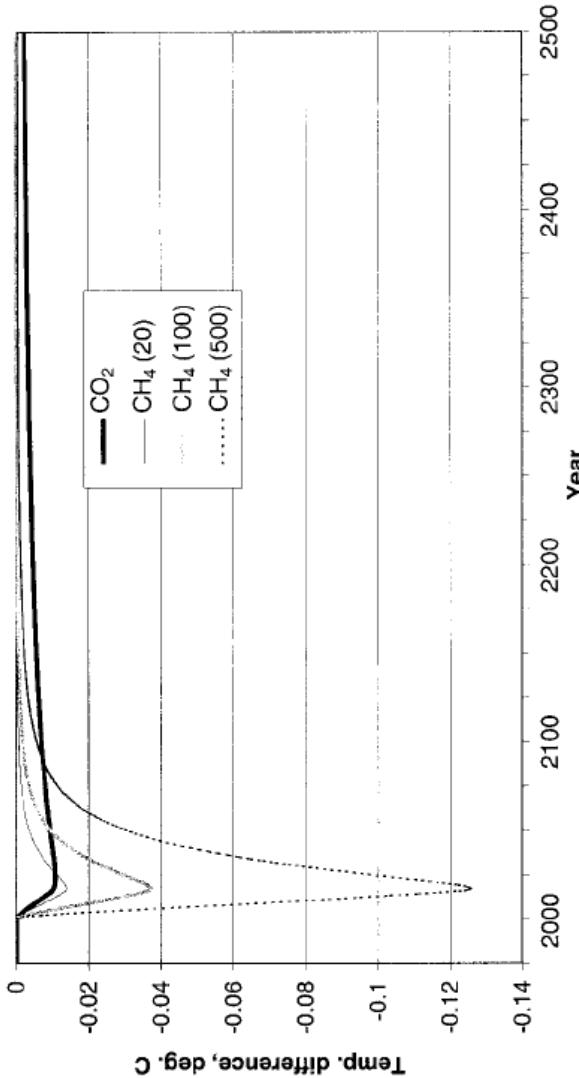

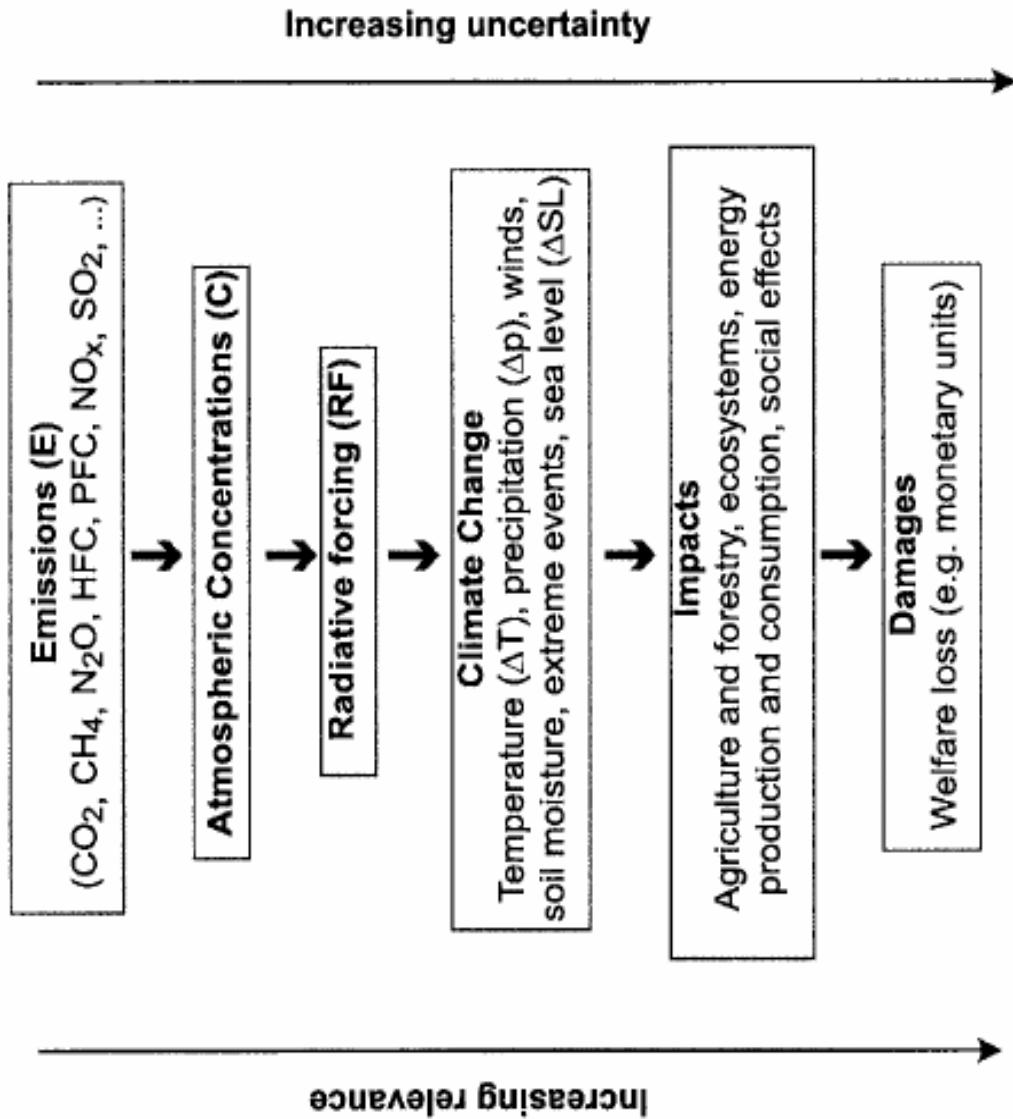

Figure 4. Temperature responses to sustained changes in emissions of CO<sub>2</sub> and CH<sub>4</sub> in terms of 'CO<sub>2</sub>-equivalents' for various time horizons. The reductions are assumed to last for 15 years.

# Contents

- A bit of background
- Comparing the emissions – the Kyoto Way
- Beyond Kyoto?
- Aviation – an extreme example
- Carbon capture and storage

# Trade-off: relevance VS. certainty & feasibility

# Choice of climate impact

# Choices for metrics

- What parameter? e.g.  $\Delta$ forcing,  $\Delta$ temperature,  $\Delta$ sea-level,  $\Delta$ damage ( $\propto \Delta T^n$ ), or  $(d/dt)$  of these?
- What emission? Pulse, sustained, ...?
- Value at a given time or integrated over a given “time horizon”?
- “discounted” so that changes in near-future are more important than changes in far-future ( $\propto e^{-rt}$ )?

The above choices affect decisions as to whether to it is best to cut short-lived or long-lived gases

# Contents

- A bit of background
- Comparing the emissions – the Kyoto Way
- Beyond Kyoto?
- Aviation – an extreme example
- Carbon capture and storage

# How aircraft can alter climate

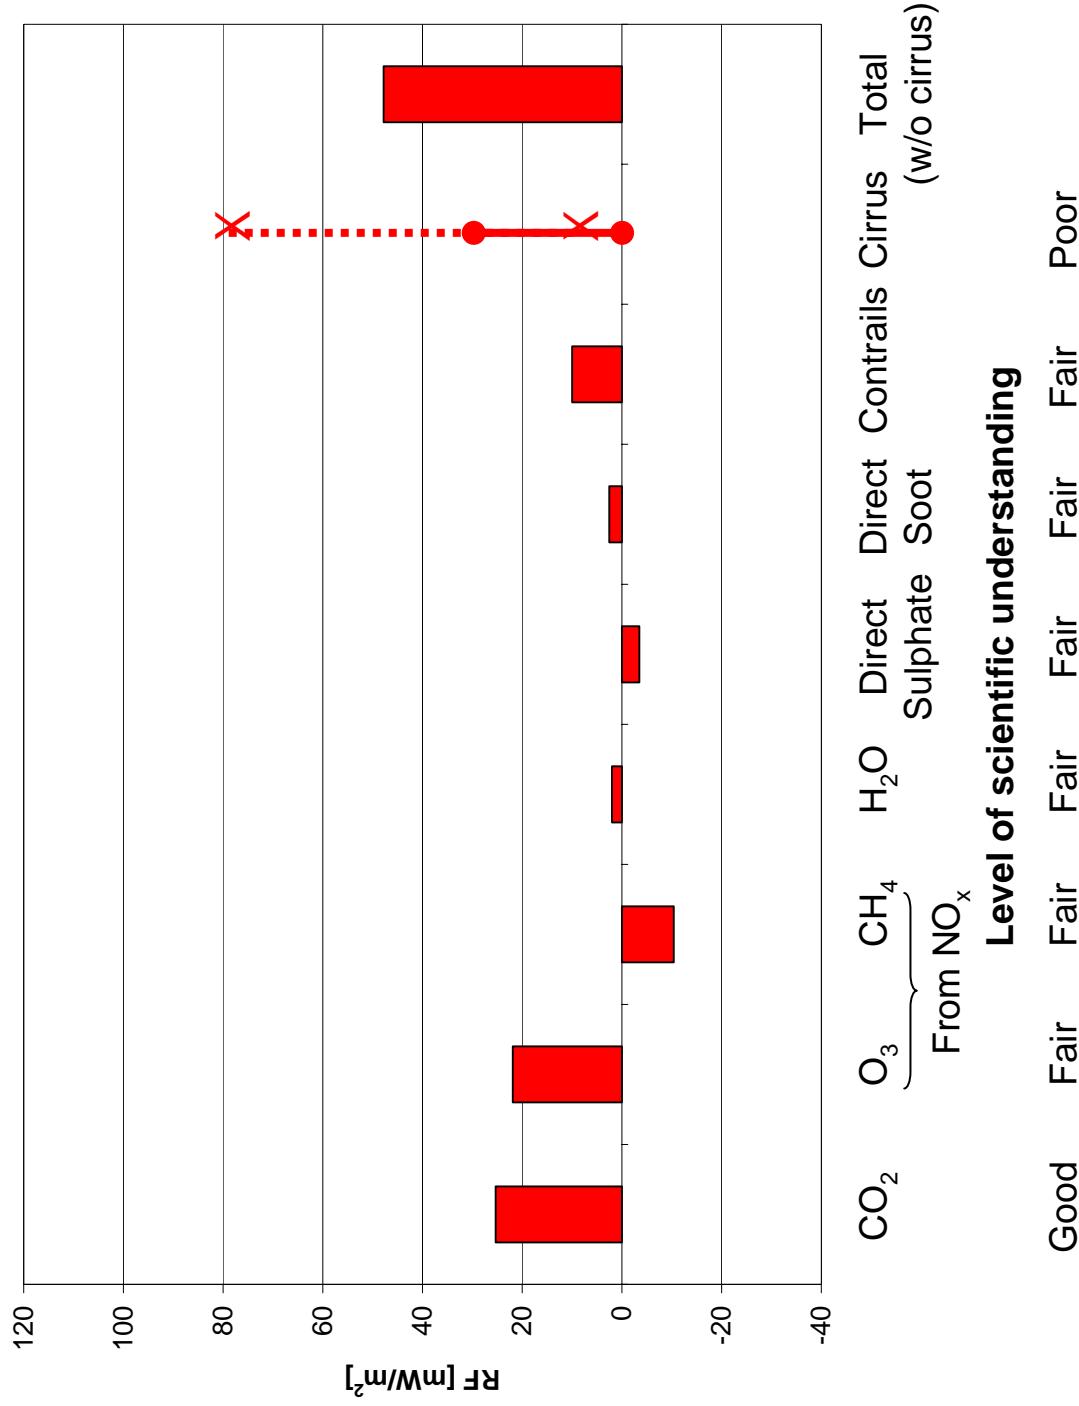

- Carbon dioxide ( $\text{CO}_2$ ) – “easy!”  
And the “non- $\text{CO}_2$ ” effects:
  - Oxides of nitrogen – complicated!
  - Contrails – uncertain!
  - Aviation-induced cirrus – ugh!
  - ...

- Massive range of different timescales

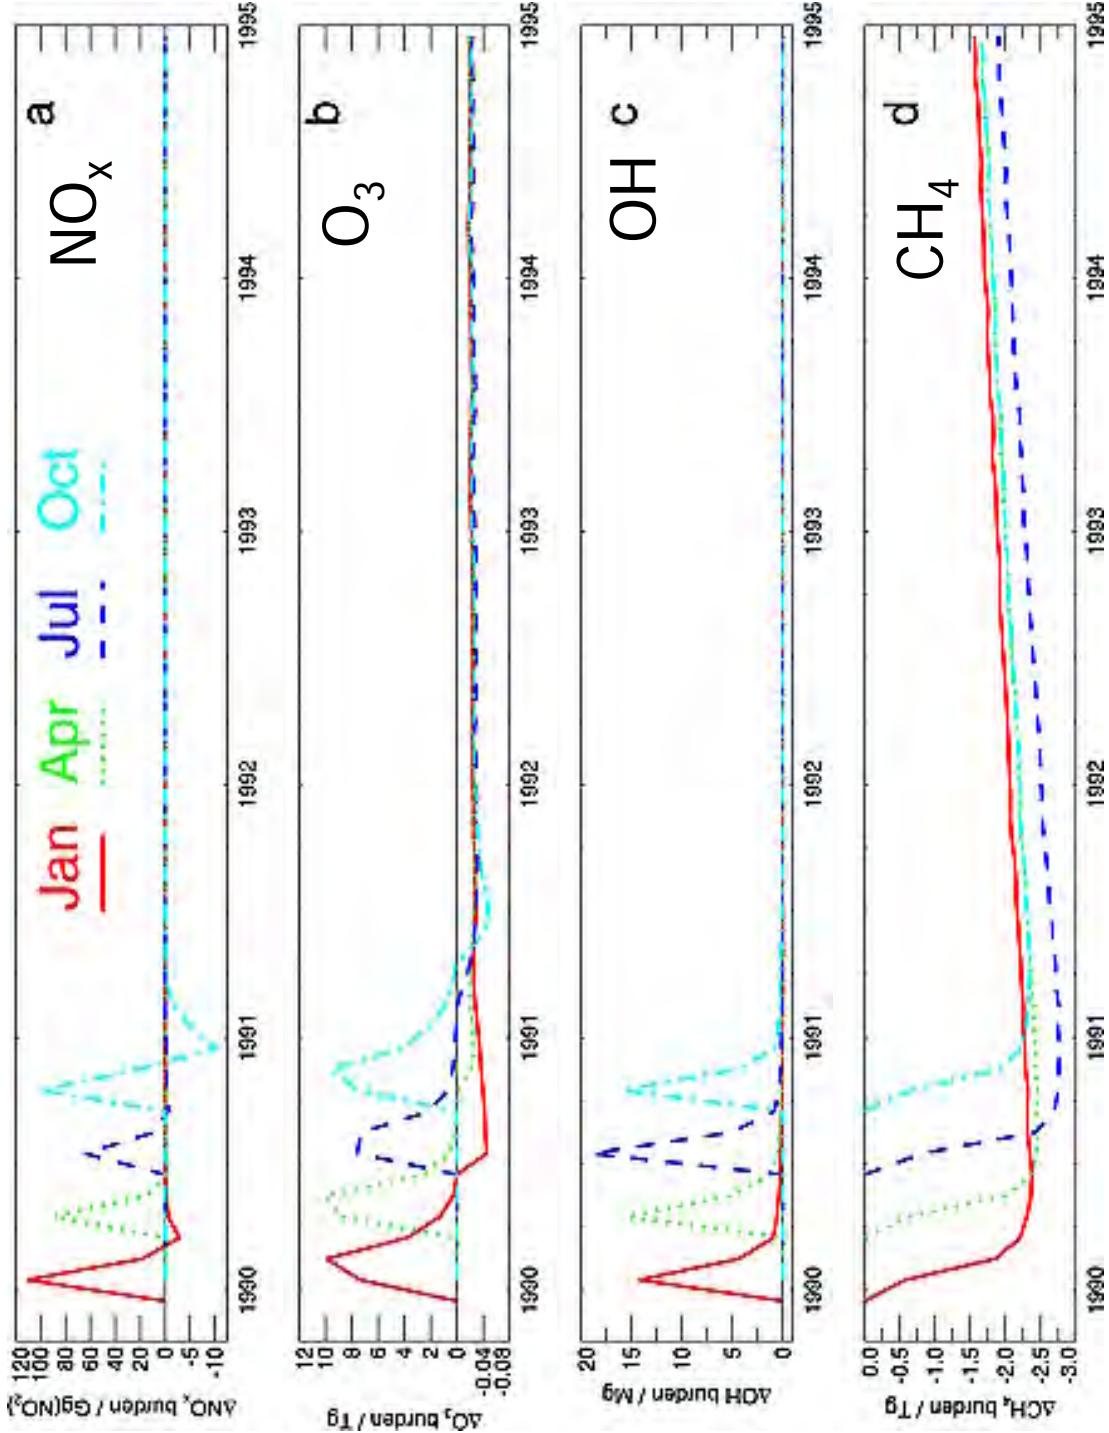

- And how do we compare one emission versus another when they are so different?

# Radiative forcing from aircraft

Sausen et al 2005

# Ozone-methane compensation due to NO<sub>x</sub> aircraft emissions

# Oxides of nitrogen ( $\text{NO}_x$ )

- $\text{NO}_x$  emissions lead to ozone *formation* – a greenhouse gas
- But *destroy* methane ... another greenhouse gas
- Which also leads to ... etc.
- The effect depends strongly on the height and location of the aircraft
- The ozone effect is mostly in northern hemisphere – the methane effect is global – to what extent do they really cancel?

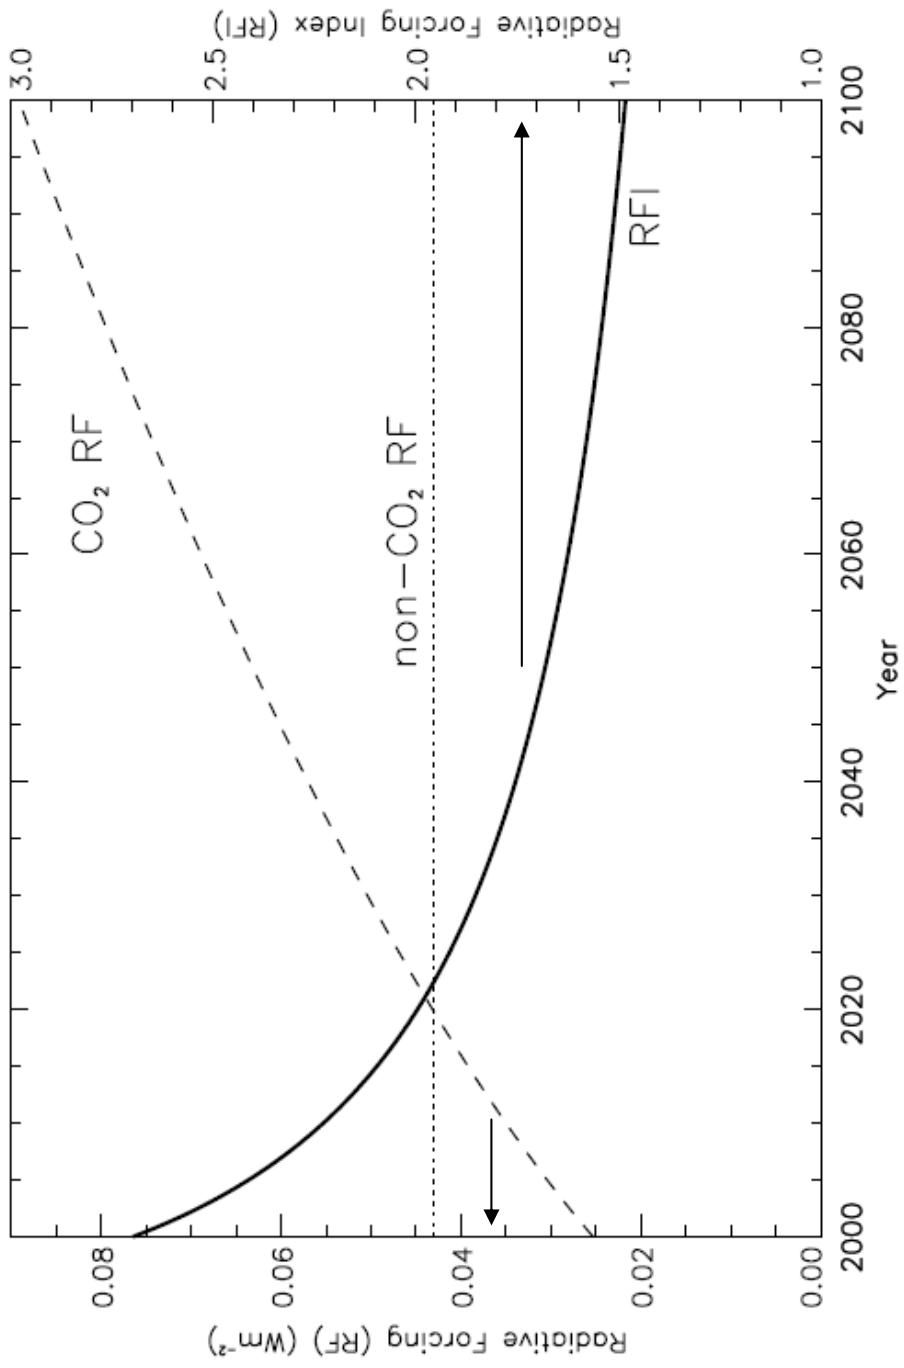

# Contrails

- Different types ... short-lived and persistent
- Formation depends *strongly* on atmospheric conditions
- Quite subtle changes in altitude or location of aircraft can have big effects on contrail formation
- Contrails reflect sunlight (cooling) and trap infrared energy (warming) – makes calculating the net effect difficult
- Inadequate observations of some important contrail properties – extent, thickness, ...

# The aviation multiplier ... the radiative forcing index (RFI)

- Some legislators and carbon-offset companies suggest multiplying the CO<sub>2</sub> emitted by aircraft by some factor – the so-called RFI - (e.g. 2.7) to account for the non-CO<sub>2</sub> effect
- Is this a “safe” thing to do? The non-CO<sub>2</sub> effects are short-lived, unlike the CO<sub>2</sub> effect
  - “Equity” with other sectors?

# Test of the RFI concept ...

Other forcings quickly in equilibrium – but CO<sub>2</sub> continues to rise

# A tentative attempt at a "rational" aviation weighting

Time horizon (2000 start)	CO <sub>2</sub> AGWP	CH <sub>4</sub> and O <sub>3</sub> NET AGWP	Contrail AGWP	CO <sub>2</sub> EWF
1	0.25	1.94	1.8	16
20	2.65	0.34	1.8	1.8
100	9.15	-0.038	1.8	1.2
500	29.9	-0.038	1.8	1.1

Units of AGWP are  $10^{-14} \text{ W m}^{-2} \text{ kg CO}_2^{-1}$  year. The appropriate CO<sub>2</sub> Emission-Weighting Factor (EWF) for the total aviation effect at the given time horizon is given in the last column. This is the sum of the middle three columns divided by the CO<sub>2</sub> AGWP.

# Carbon Capture and Storage

With thanks to my collaborators: **Emma Stone** (now University of Bristol) and **Jason Lowe** (Hadley Centre, Met Office (Reading)) – all figures from Stone et al. (submitted 2007)

(IPCC 2005)

# Problem

- Carbon capture and storage requires energy! i.e. the generation of a given amount of energy from fossil-fuel means extra CO<sub>2</sub> is produced
- But CO<sub>2</sub> will leak out of its storage reservoirs
- **Can we be sure that CCS doesn't lead to increased CO<sub>2</sub> in the atmosphere?!**

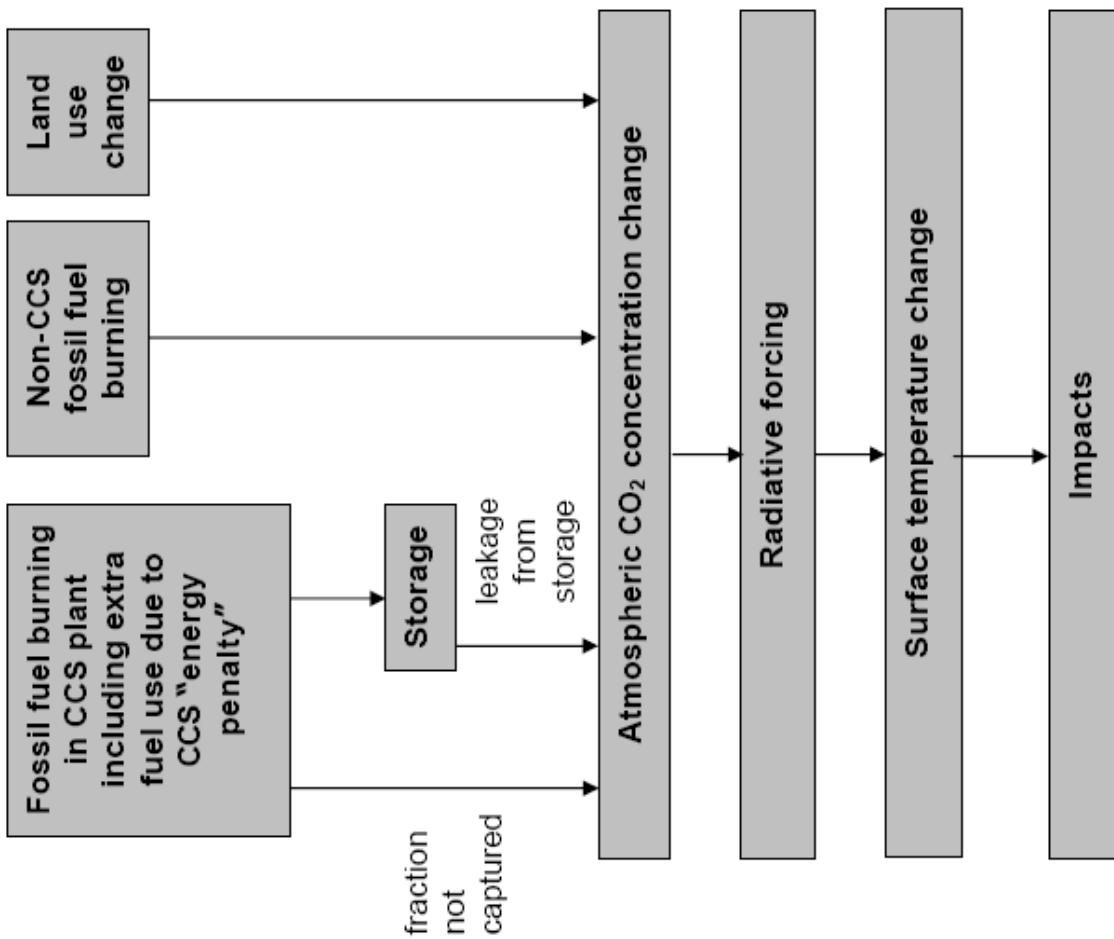

# Approach

- Couple together three simple models:

A carbon capture model

A carbon cycle model

A climate model

# Key inputs to CCS model

- *Energy penalty*: fractional increase in CO<sub>2</sub> production for a given energy generation due to implementation of CCS
- *Fraction of CO<sub>2</sub> captured*: in an individual CCS plant, how much of the CO<sub>2</sub> is actually captured, rather than emitted directly to the atmosphere?
- *Leakage rate of CO<sub>2</sub> from reservoir (or transmission to reservoir)*: Express as a time constant in years ... and assume steady rather than catastrophic loss

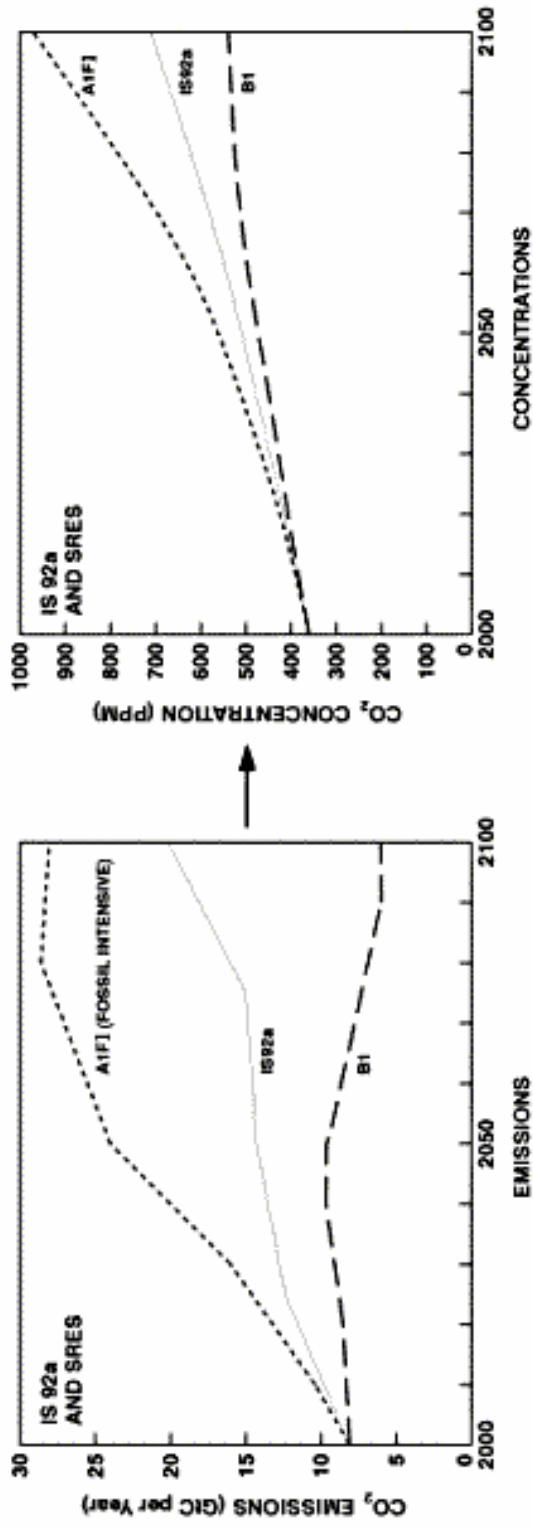

*We assume a single value for each and ignore the fact that these will be time dependent as technology improves ...*

# Chosen Parameter Space

Retention time, $\tau$ (years)	Energy penalty, $\alpha$	Fraction of fossil fuel emissions released from a single CCS plant, $\beta$	Fraction of global fossil fuels emissions subject to CCS, $\gamma$
10	0.10	0.05	0.25
40	<b>0.25</b>	<b>0.1</b>	<b>0.50</b>
100	0.40	0.15	
500			
1000			

# Emission scenarios

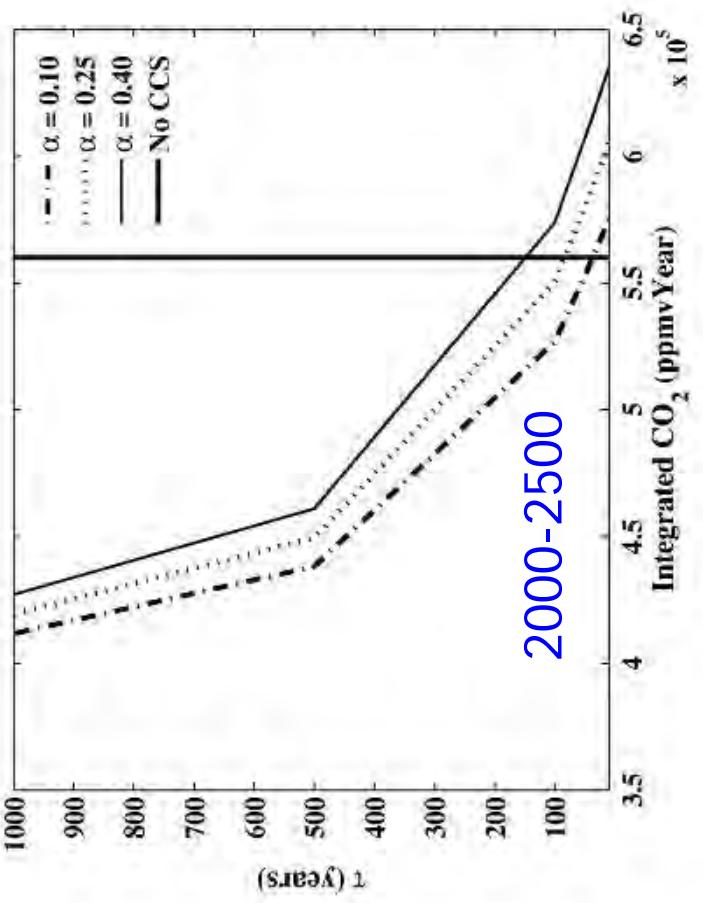

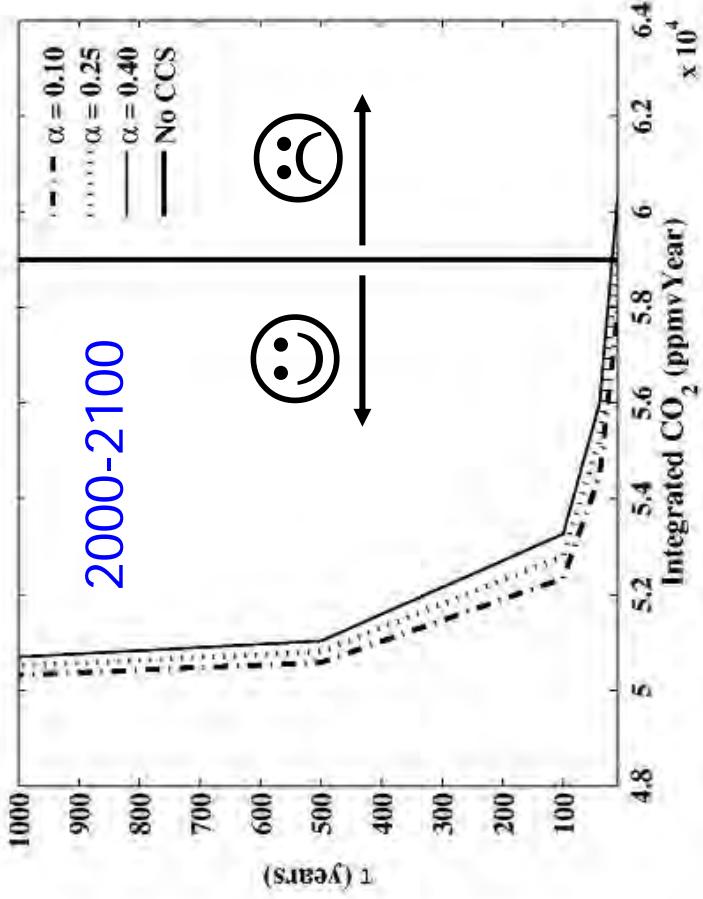

Need to specify the background emission scenario on which the CCS operates – assume two quite “extreme” cases – a fossil-fuel intensive world and a “greener” world from IPCC scenarios

# How do we measure effectiveness of CCS?

- Need to choose timescale ... here we use 2000-2100 and 2000-2500 (!)
- Need to choose metric ... we use time-integrated CO<sub>2</sub> concentration, time-integrated radiative forcing and time-integrated temperature change (and compare calculations with and without CCS)

# Integrated CO<sub>2</sub>

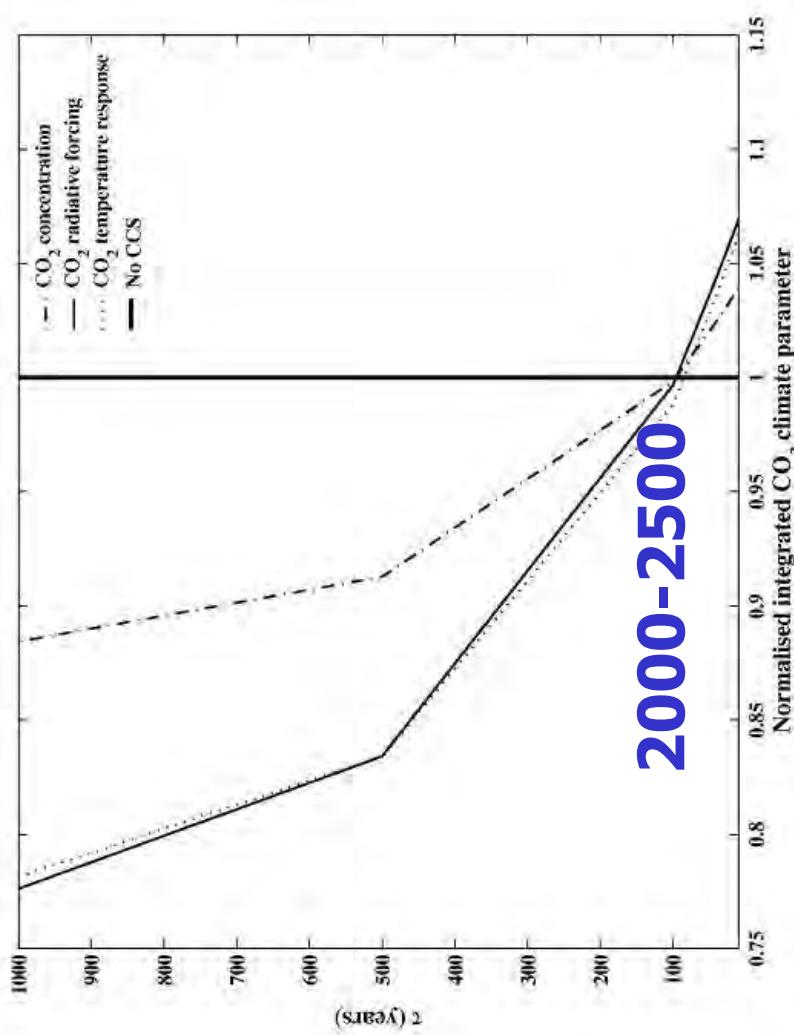

$\alpha$  is the energy penalty

Benefit of increase in retention time decreases with  
retention time

For the longer time period, greater retention times  
are necessary for break-even

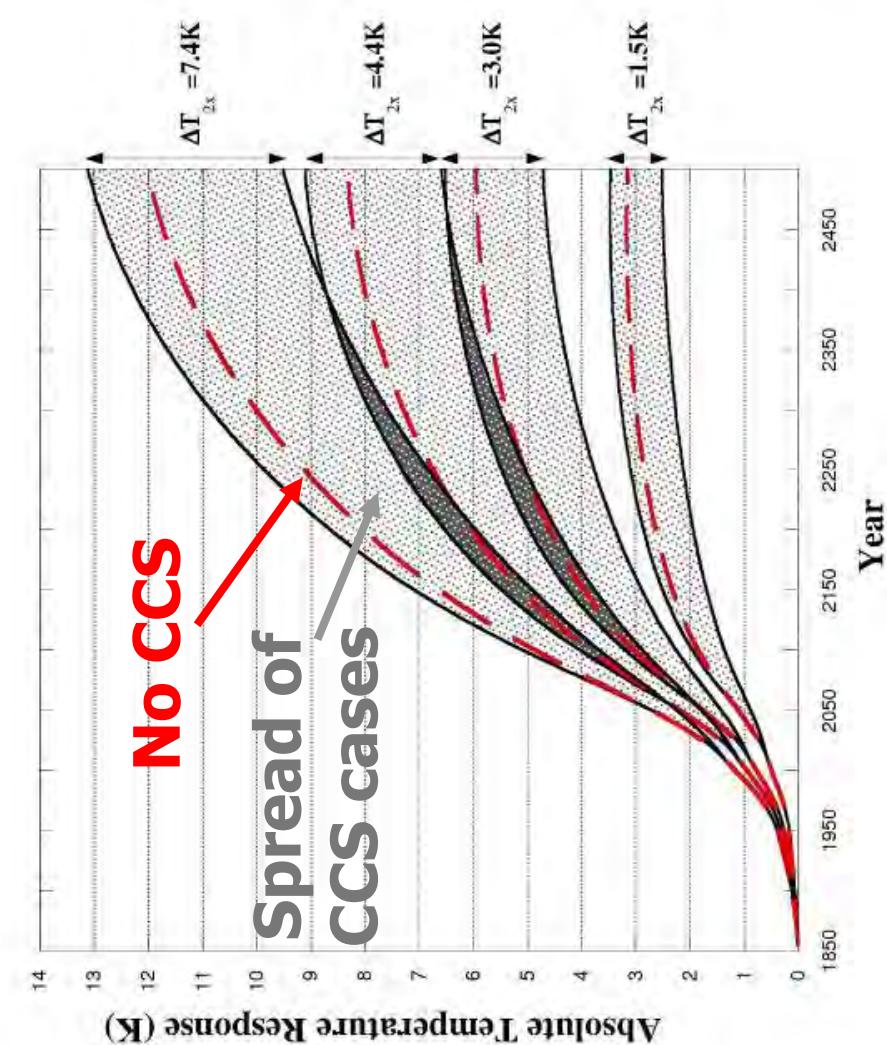

# Impact of using other metrics

- Little impact on the “break-even” reservoir retention time, but the perceived fractional benefit varies.

# Effect of uncertainty in climate sensitivity

- Example of “fossil intensive” scenario
  - Over shorter time periods, almost all CCS cases are beneficial – less so, over long time periods
- Absolute benefit depends on climate sensitivity (and on emissions scenario)

# Break-even retention times (in years) for 2000-2500 integrated CO<sub>2</sub>

Scenario	Alpha
	0.1
	0.25
A1FI	36
B1	42
	0.40
	83
	96
	125
	144

Obviously, the greater the energy penalty, the more stringent conditions there are on reservoir leakage

# Conclusions

- In general, no clear consensus on which metrics are to be used to compare different emissions – nor obvious choice of which “time horizon” is appropriate
- For CCS, our *simple* model indicates that provided reservoir times are greater than about 200 years, CCS should be beneficial

# Carbon sequestration in sediments containing ferric iron

September 13, 2007

Susana Garcia and  
M. Mercedes Maroto-Valer

School of Chemical and Environmental Engineering,  
Nottingham, United Kingdom

The University of  
Nottingham

CICCS [centre for innovation in carbon capture and storage]

# Outline

## Introduction

- Carbon dioxide capture and storage (CCS)
- CO<sub>2</sub> geological storage
- Estimates of CO<sub>2</sub> storage costs

## Part 1

- Ferric-iron bearing sediments
- Objectives
- Study samples

## Part 2

- Research plan
- Novel experimental set-up and methodology
- Preliminary results

## Conclusions

# CO<sub>2</sub> capture and geological storage

1. Capture from a large point source
2. Injection into suitable deep rock formations

## A FOUR STEP PROCESS:

# CO<sub>2</sub> Geological Storage

Possible storage formations

Saline formations

Deep coal seams

Oil and gas fields

The University of  
Nottingham

CICCS [centre for innovation in carbon capture and storage]

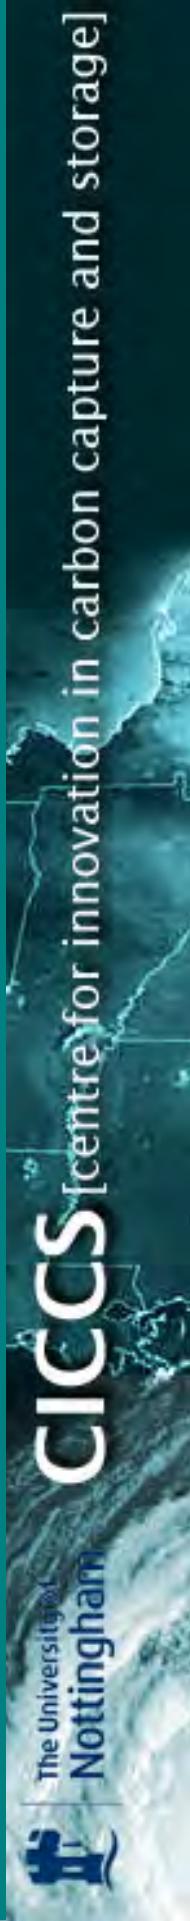

# Global capacity of geological reservoirs

Emissions from combustion of fossil fuels = 22 Gt CO<sub>2</sub>/year

Reservoir type	Lower estimate of storage capacity (GtCO <sub>2</sub> )	Upper estimate of storage capacity (GtCO <sub>2</sub> )
Oil and gas fields	670*	900*
Unminable coal seams (ECBM)	3-15	200
Deep saline formations	1,000	Uncertain, but possibly 10 <sup>4</sup>

\* These numbers would increase by 25% if 'undiscovered' oil and gas fields were included in this assessment.

Source: IPCC Special Report on CCS, 2005

# Estimates of CO<sub>2</sub> storage costs

Option	Representative Cost Range (US\$/tonne CO <sub>2</sub> stored)	Representative Cost Range (US\$/tonne C stored)
Geological - Storage <sup>a</sup>	0.5-8.0	2-29
Geological - Monitoring	0.1-0.3	0.4-1.1
Ocean <sup>b</sup>		
Pipeline	6-31	22-114
Ship (Platform or Moving Ship Injection)	12-16	44-59
Mineral Carbonation <sup>c</sup>	50-100	180-370

<sup>a</sup> Does not include monitoring costs.

<sup>b</sup> Includes offshore transportation costs; range represents 100-500 km distance offshore and 3000 m depth.

<sup>c</sup> Unlike geological and ocean storage, mineral carbonation requires significant energy inputs equivalent to approximately 40% of the power plant output.

Source: IPCC Special Report on CCS, 2005

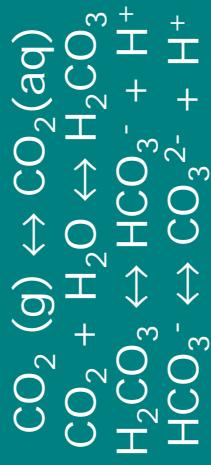

# **CO<sub>2</sub> Geological Storage**

- CO<sub>2</sub> storage mechanisms in geological formations

Physical trapping: Hydrodynamic trapping

Geochemical trapping:

1. Solubility trapping    

2. Mineral trapping    

- Sediments considered so far:

Ca-bearing arkosic

Mg-bearing illitic

Feld-bearing glauconitic

The University of  
Nottingham

**CICCS** [Centre for innovation in carbon capture and storage]

# Ferric-iron bearing sediments

- Their potential usage has been suggested lately (*Palandri, J.L. et al, 2005*)

- Advantages versus sediments considered so far:
  - Widespread geographic distribution and great thickness
  - High porosity and permeability
  - Less expensive/less energy demanding  $\text{CO}_2$  capture process

- Reductant agent needed for the process to take place
  - $\downarrow \text{SO}_2$
  - $\uparrow \text{H}_2$

# Acid gas injection

- Acid gas: mixture of H<sub>2</sub>S and CO<sub>2</sub> with minor amounts of hydrocarbon gases
- It occurs at 44 different locations across the Alberta Basin (Alberta and British Columbia)

Mature and safe technology

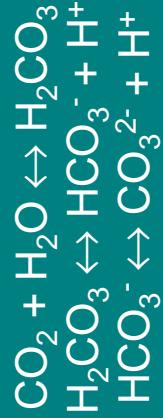

## HOWEVER...

- It has not been developed as a CO<sub>2</sub> sequestration approach
- More research is needed

# Reaction of CO<sub>2</sub>-SO<sub>2</sub> gas mixtures with ferric iron and water

- Dissolution process

- Reduction process

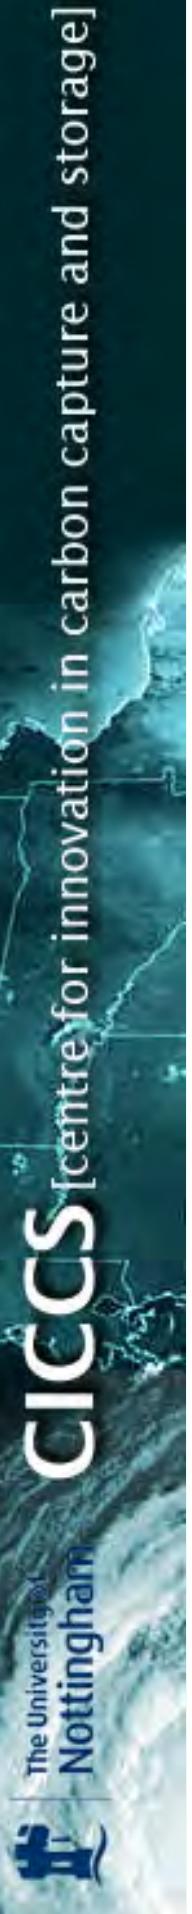

- Carbonation process

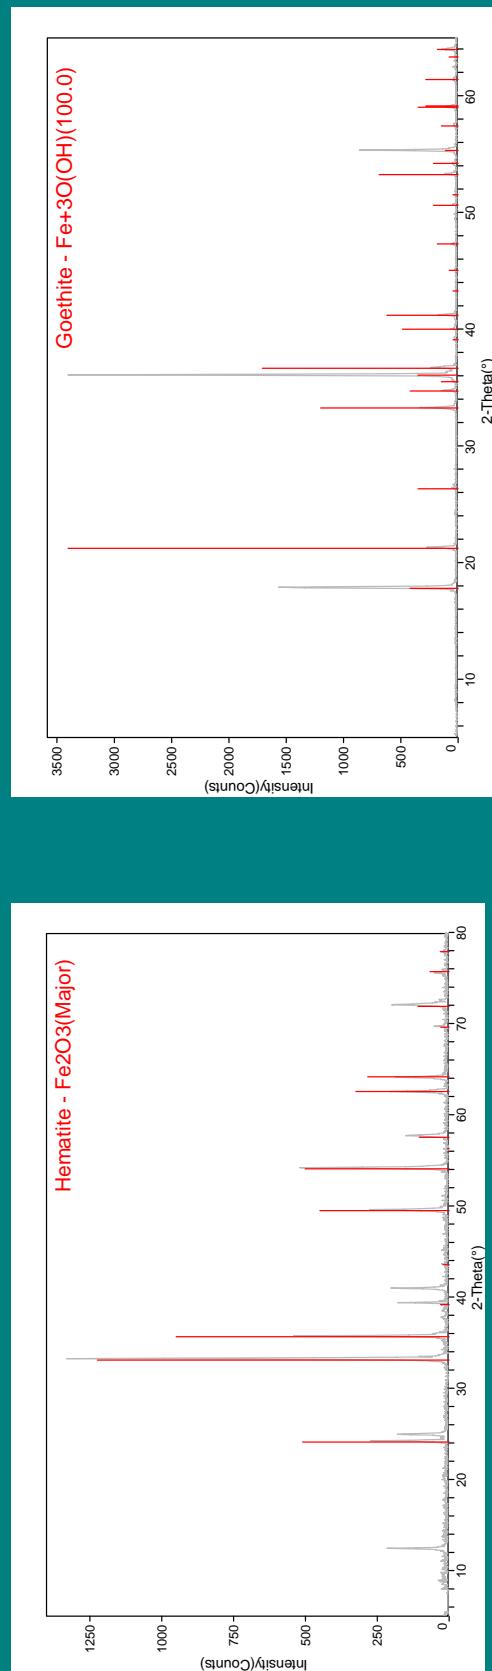

# Objectives

- Laboratory studies to proof the ferric-iron bearing sediments potential for CO<sub>2</sub> underground storage
- Experimental set-up design to run tests under different geochemical conditions
- Research plan and development of the methodology

# Study samples

- Previous researchers: Hematite sample from Gerais mines (Brazil)
- This research:
  - Hematite sample from Shishen mine (South Africa)
  - Goethite sample from El Paso County, Colorado (US)
  - Future samples: olivine, serpentine, granite and sandstone

# Research plan

**Theoretical equilibrium geochemical simulations**  
**Laboratory studies:**

## **1. Reductive dissolution of iron oxides**

CO<sub>2</sub>/SO<sub>2</sub> ratio (boiler, experiment, stoichiometric)

Reaction time (1 day, 1 week, others)

Solids concentration (25g/L, 67g/L, 100g/L)

Reaction temperature (50°C, 100 °C, 150 °C)

Reaction pressure (100 bar, 200 bar, 350 bar)

Particle size (<38 µm, 38-150 µm, 150-300 µm)

## **2. Carbonation conditions**

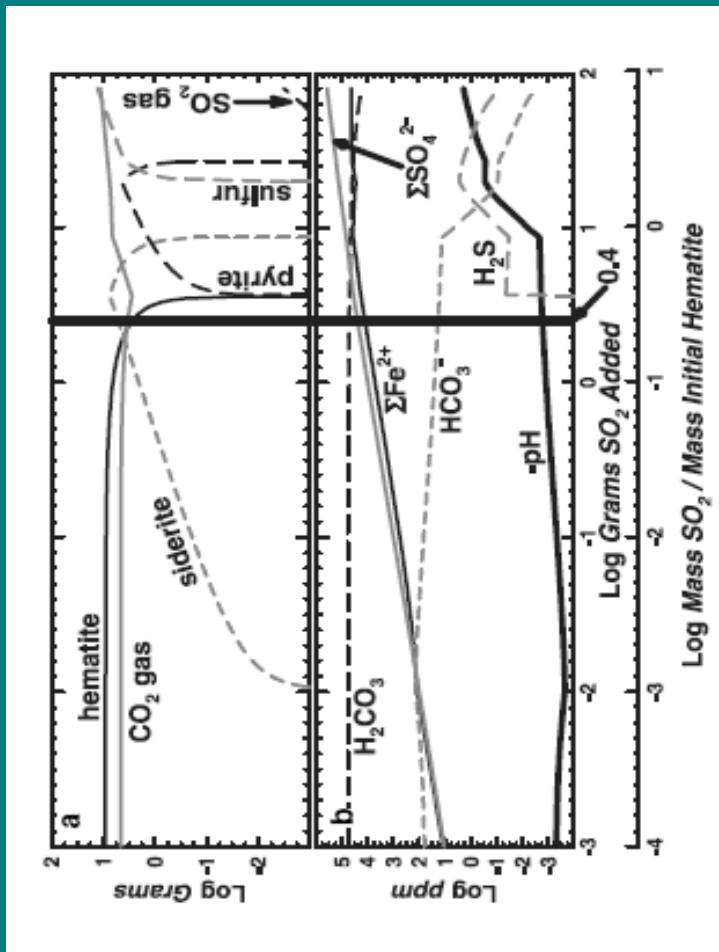

## **3. Optimization of reductive dissolution and carbonation processes**

# Theoretical equilibrium geochemical simulations

**Computer program: Chiller**

Compute reaction path in geologic systems by changing one of the systems variables incrementally and re-computing equilibrium at each step.

**Follow-up of work by  
Palandri J.L., Rosenbauer  
R.J. and Kharaka Y.K.**

Results summary from simulation at 150°C and 300 bar of the CO<sub>2</sub>-SO<sub>2</sub> reaction with 10 gr of hematite in 156 gr of 1.0M NaCl brine using 14 gr (excess) CO<sub>2</sub> (Palandri J.L. et al, 2005)

The University of  
Nottingham

**CICCS** [centre for innovation in carbon capture and storage]

# Research plan

**Theoretical equilibrium geochemical simulations**  
**Laboratory studies:**

## **1. Reductive dissolution of iron oxides**

CO<sub>2</sub>/SO<sub>2</sub> ratio (boiler, experiment, stoichiometric)

Reaction time (1 day, 1 week, others)

Solids concentration (25g/L, 67g/L, 100g/L)

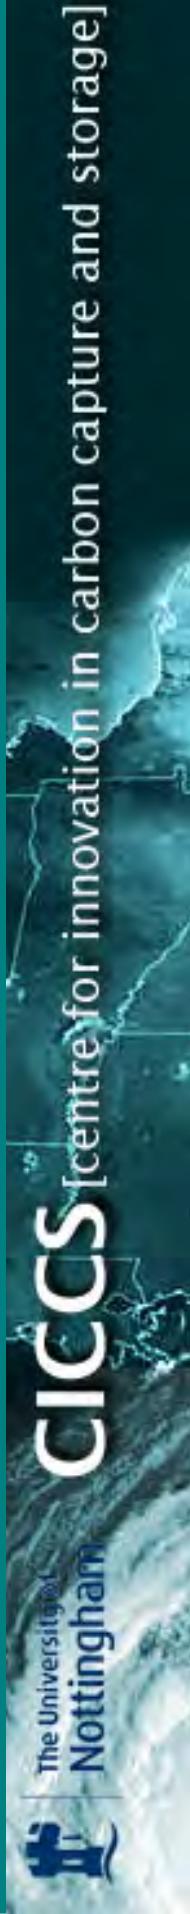

Reaction temperature (50°C, 100 °C, 150 °C)

Reaction pressure (100 bar, 200 bar, 350 bar)

Particle size (<38 µm, 38-150 µm, 150-300 µm)

## **2. Carbonation conditions**

## **3. Optimization of reductive dissolution and carbonation processes**

# Previous experimental work

- **Experimental apparatus**

Autoclave containing a flexible Au-Ti reaction cell with ~ 200 ml total volume.

- **Experimental conditions**

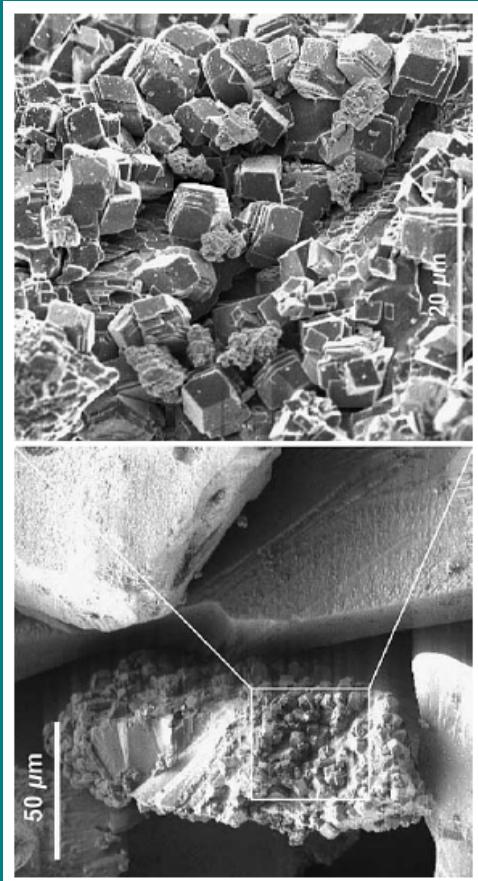

Temperature = 150°C

Pressure = 300 bar

CO<sub>2</sub>/SO<sub>2</sub> ratio ~ 9:1

Brine volume (1.0 m NaCl) = 150 ml

Solids concentration = 67 g/L

Experimental results, solids: siderite on etched hematite (Palandri J.L. et al., 2005)

Only **ONE** experiment reported so far ...

# Research plan

**Theoretical equilibrium geochemical simulations**  
**Laboratory studies:**

## **1. Reductive dissolution of iron oxides**

CO<sub>2</sub>/SO<sub>2</sub> ratio (boiler, experiment, stoichiometric)

Reaction time (1 day, 1 week, others)

Solids concentration (25g/L, 67g/L, 100g/L)

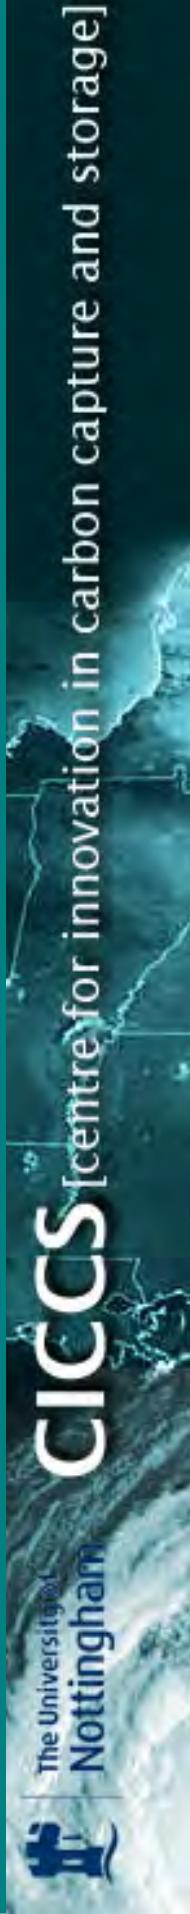

Reaction temperature (50°C, 100 °C, 150 °C)

Reaction pressure (100 bar, 200 bar, 350 bar)

Particle size (<38 µm, 38-150 µm, 150-300 µm)

## **2. Carbonation conditions**

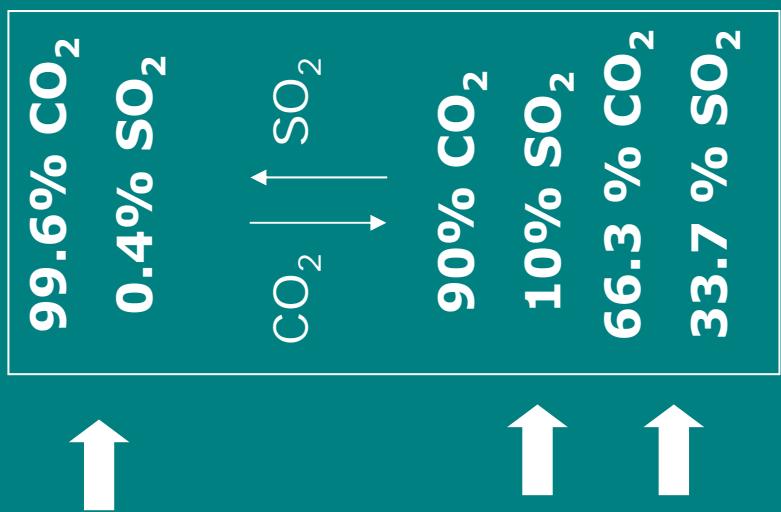

## **3. Optimization of reductive dissolution and carbonation processes**

# $\text{CO}_2/\text{SO}_2$ ratios

- Boiler ratio

	By Mass		By Volume	
	From boiler	Stack	From boiler	Stack
$\text{CO}_2$	17.527%	17.159%	<b>11.765%</b>	11.340%
$\text{N}_2$	70.204%	68.559%	73.987%	71.137%
Ar	1.188%	1.160%	0.878%	0.845%
$\text{O}_2$	6.531%	6.374%	6.030%	5.795%
$\text{H}_2\text{O}$	4.447%	6.739%	7.291%	10.879%
$\text{SO}_2$	0.101%	0.009%	<b>0.046%</b>	0.004%
HCl	0.002%	0.000%	0.002%	0.000%
	100.000%	100.000%	100.000%	100.000%
0.68% Sulphur Coal				

- Experiment ratio  $\rightarrow \text{CO}_2/\text{SO}_2 \approx 9:1$
- Stoichiometric ratio  $\rightarrow 2 \text{ mol CO}_2 \quad 1 \text{ mol SO}_2$

# AND...What about the SO<sub>2</sub> needed?

Significant limitation: Flue gas typically contains less than 5%wt SO<sub>2</sub>

Various options to overcome the problem:

1. Targeted sediments must contain other divalent metals (e.g., Ca, Mg, Fe<sup>II</sup>).
2. Reduced S-bearing waste gas derived from other industrial processes could be added to the waste gas stream, e.g., H<sub>2</sub>S from sour natural gas processing.

# Research plan

**Theoretical equilibrium geochemical simulations**  
**Laboratory studies:**

## **1. Reductive dissolution of iron oxides**

CO<sub>2</sub>/SO<sub>2</sub> ratio (boiler, experiment, stoichiometric)

## Particle size distribution

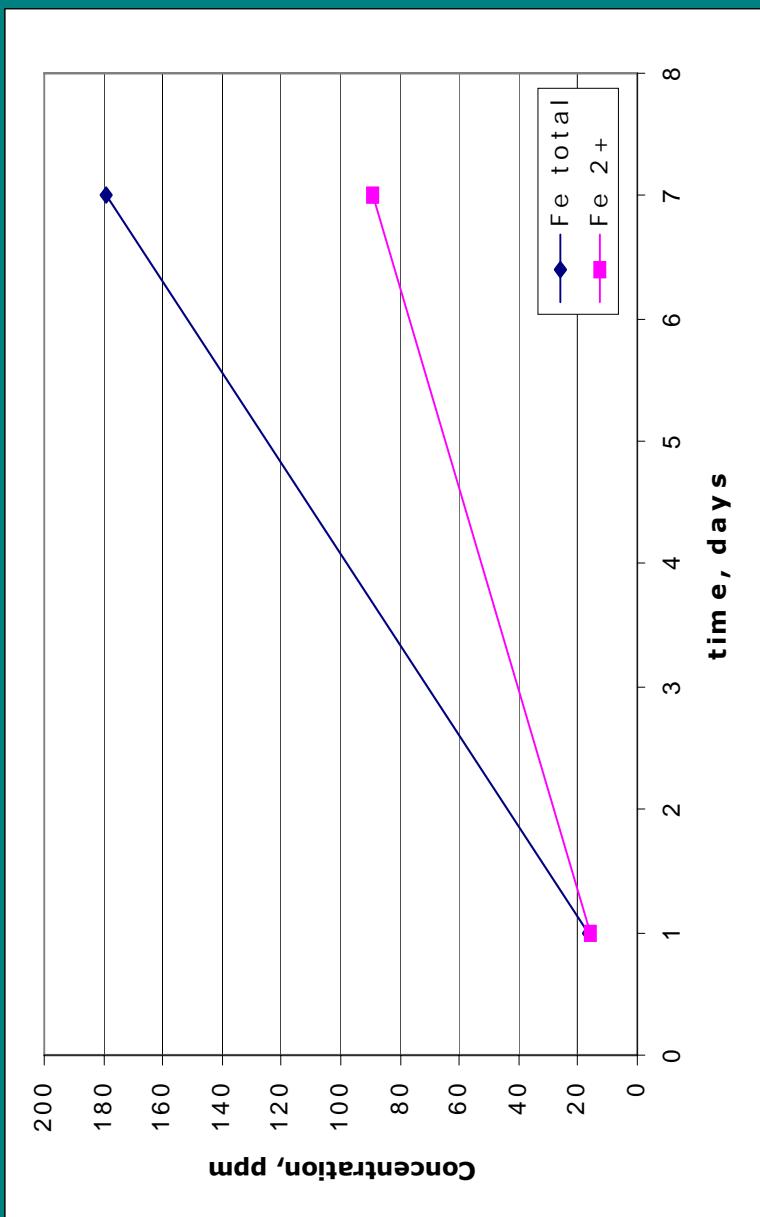

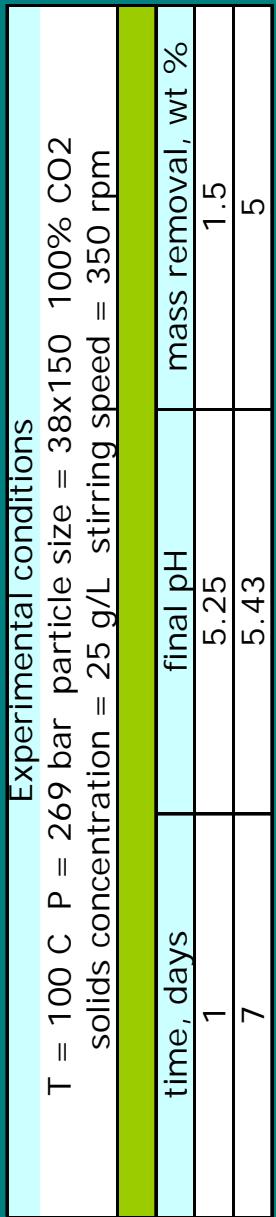

CICCS [centre for innovation in carbon capture and storage]

CICCS

The University of  
Nottingham

# Preliminary results

# Conclusions

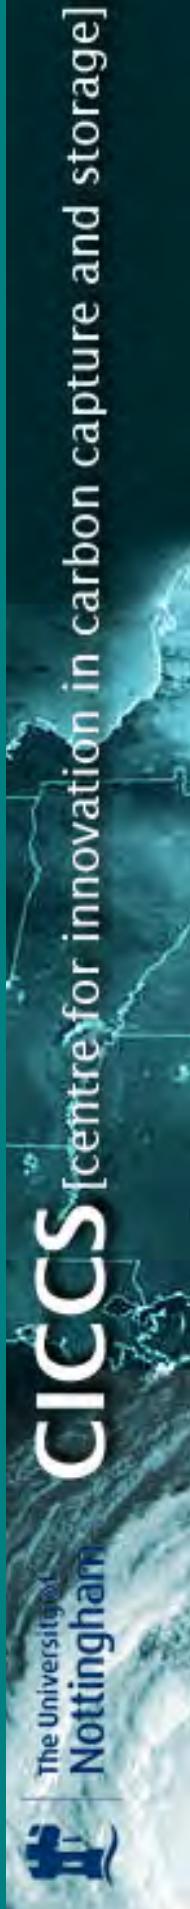

- Experimental work is needed to assess the ferric-iron bearing sediments potential to become effective reservoirs for underground CO<sub>2</sub> storage.
- A state-of-the-art experimental set-up has been designed and assembled to test previous theoretical work.
- Different iron oxide samples have been obtained and characterized as well as other silicate samples already considered for CO<sub>2</sub> sequestration.
- This research will provide empirical and novel data concerning CO<sub>2</sub>/SO<sub>2</sub> injection into saline aquifers with different rock formations.
- Data will help validation of the different geochemical simulations already conducted within the acid gas injection research field.

# Acknowledgements

The authors would also like to thank **R. Rosenbauer and J. Palandri** for their support in this research.

# Amine scrubbing for CO<sub>2</sub> capture from power plant flue gas

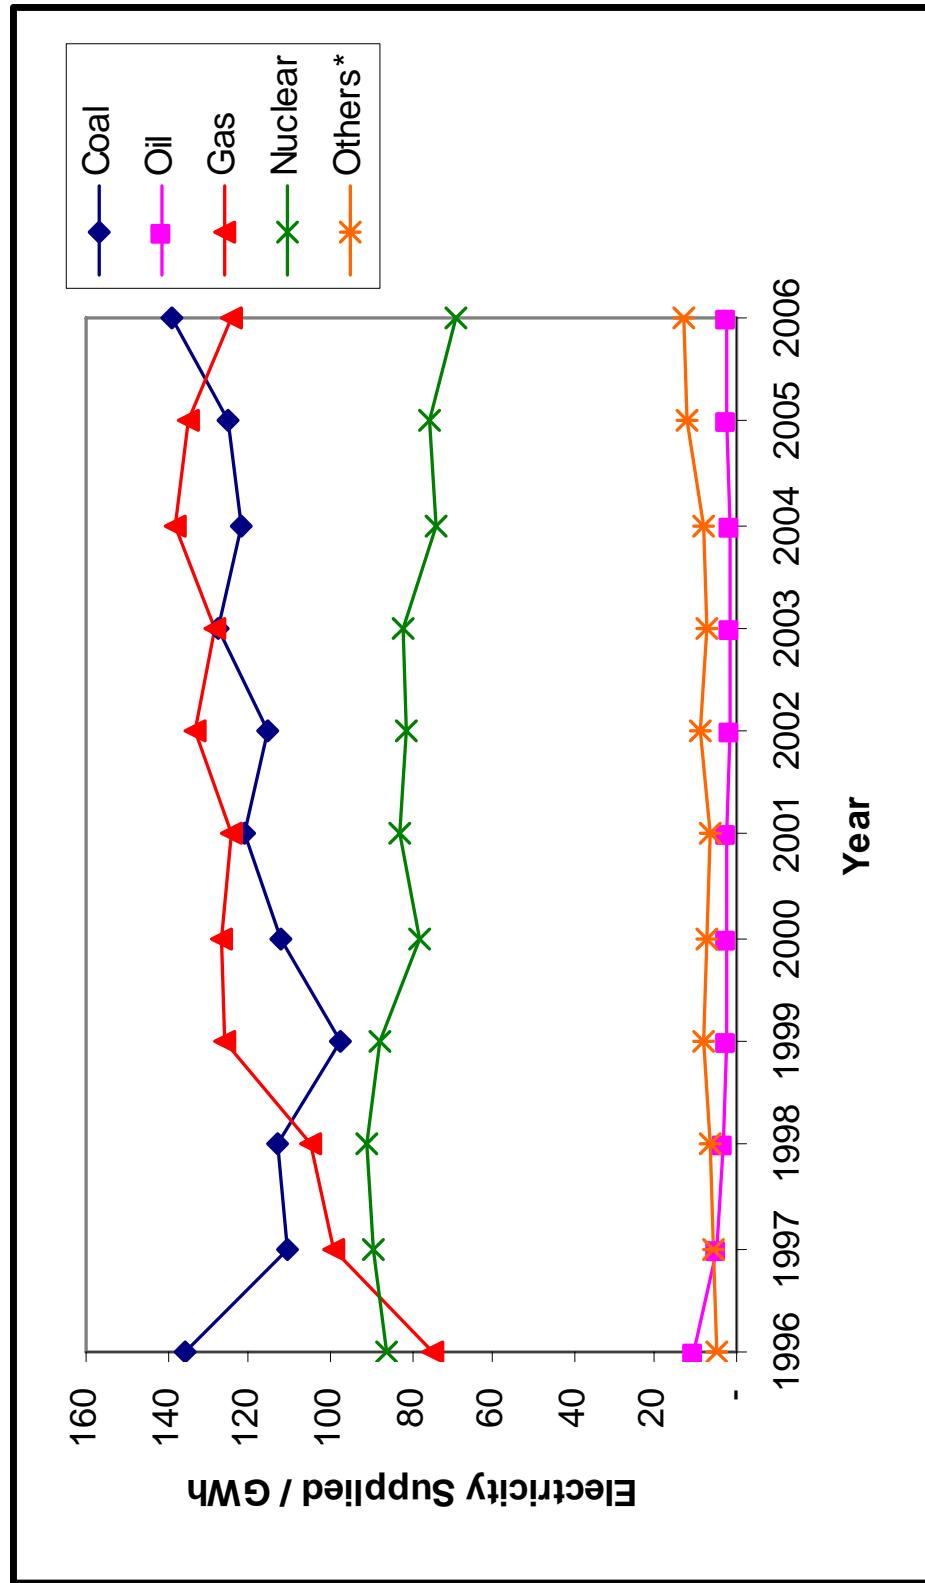

Nick Booth

Future Energy: Chemical Solutions  
12-14<sup>th</sup> September 2007

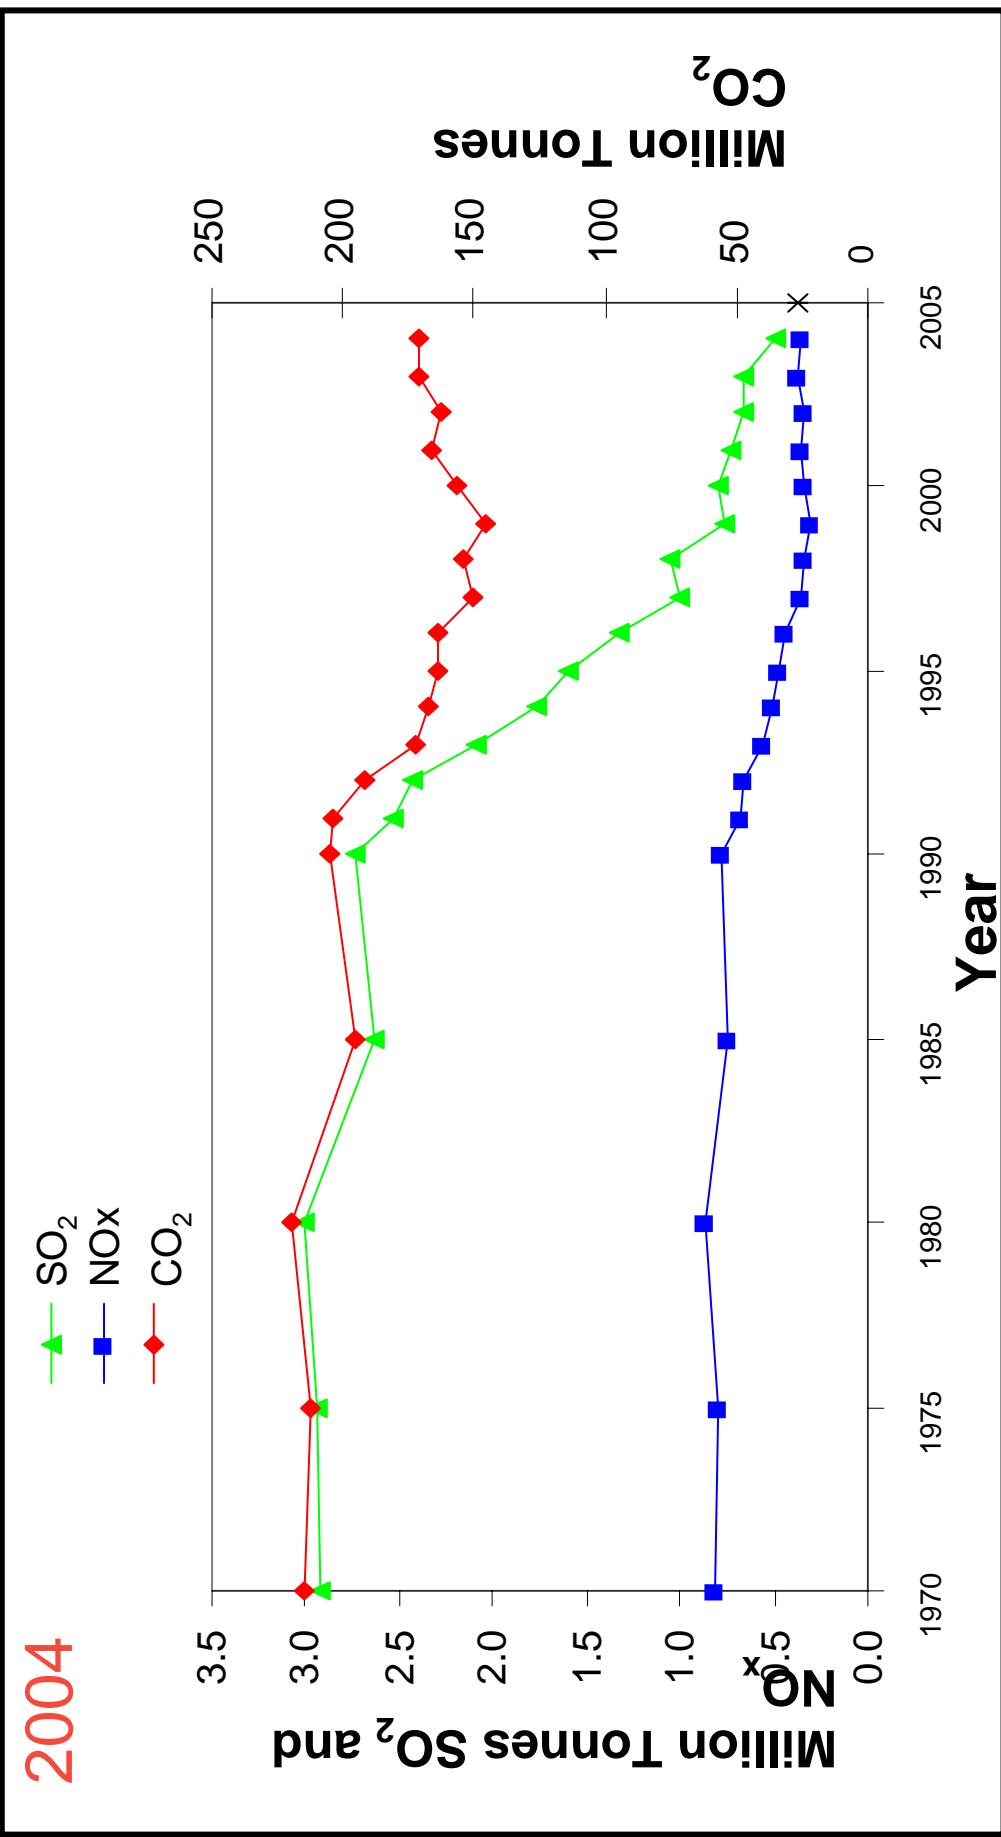

## Overview

- UK Electricity production by fuel type
- Reducing power station CO<sub>2</sub> emissions
  - Track 1: Efficiency
  - Track 2: Carbon capture and storage
- Amine scrubbing process and chemistry
- Advantages and challenges
- Development activities
- Conclusions

## UK electricity supply 1996 – 2006 by fuel type

Source: [http://stats.berr.gov.uk/energystats/dukes5\\_6.xls](http://stats.berr.gov.uk/energystats/dukes5_6.xls)

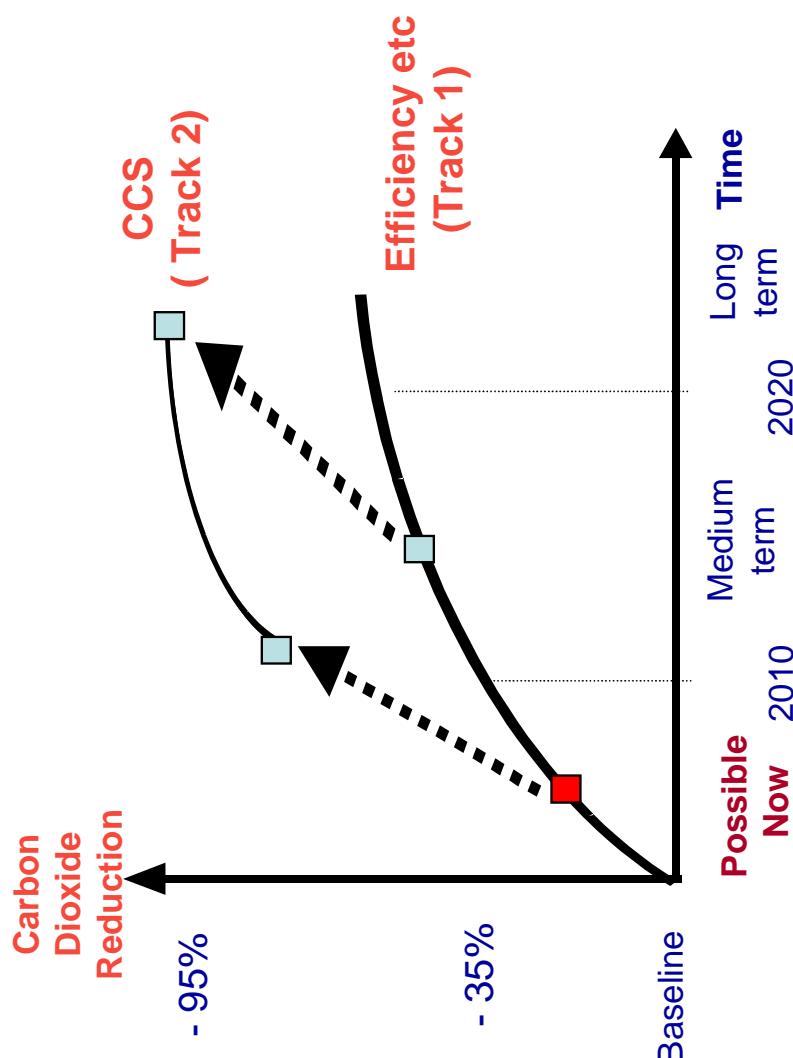

## UK power station emissions of SO<sub>2</sub>, NO<sub>x</sub> and CO<sub>2</sub> 1970-

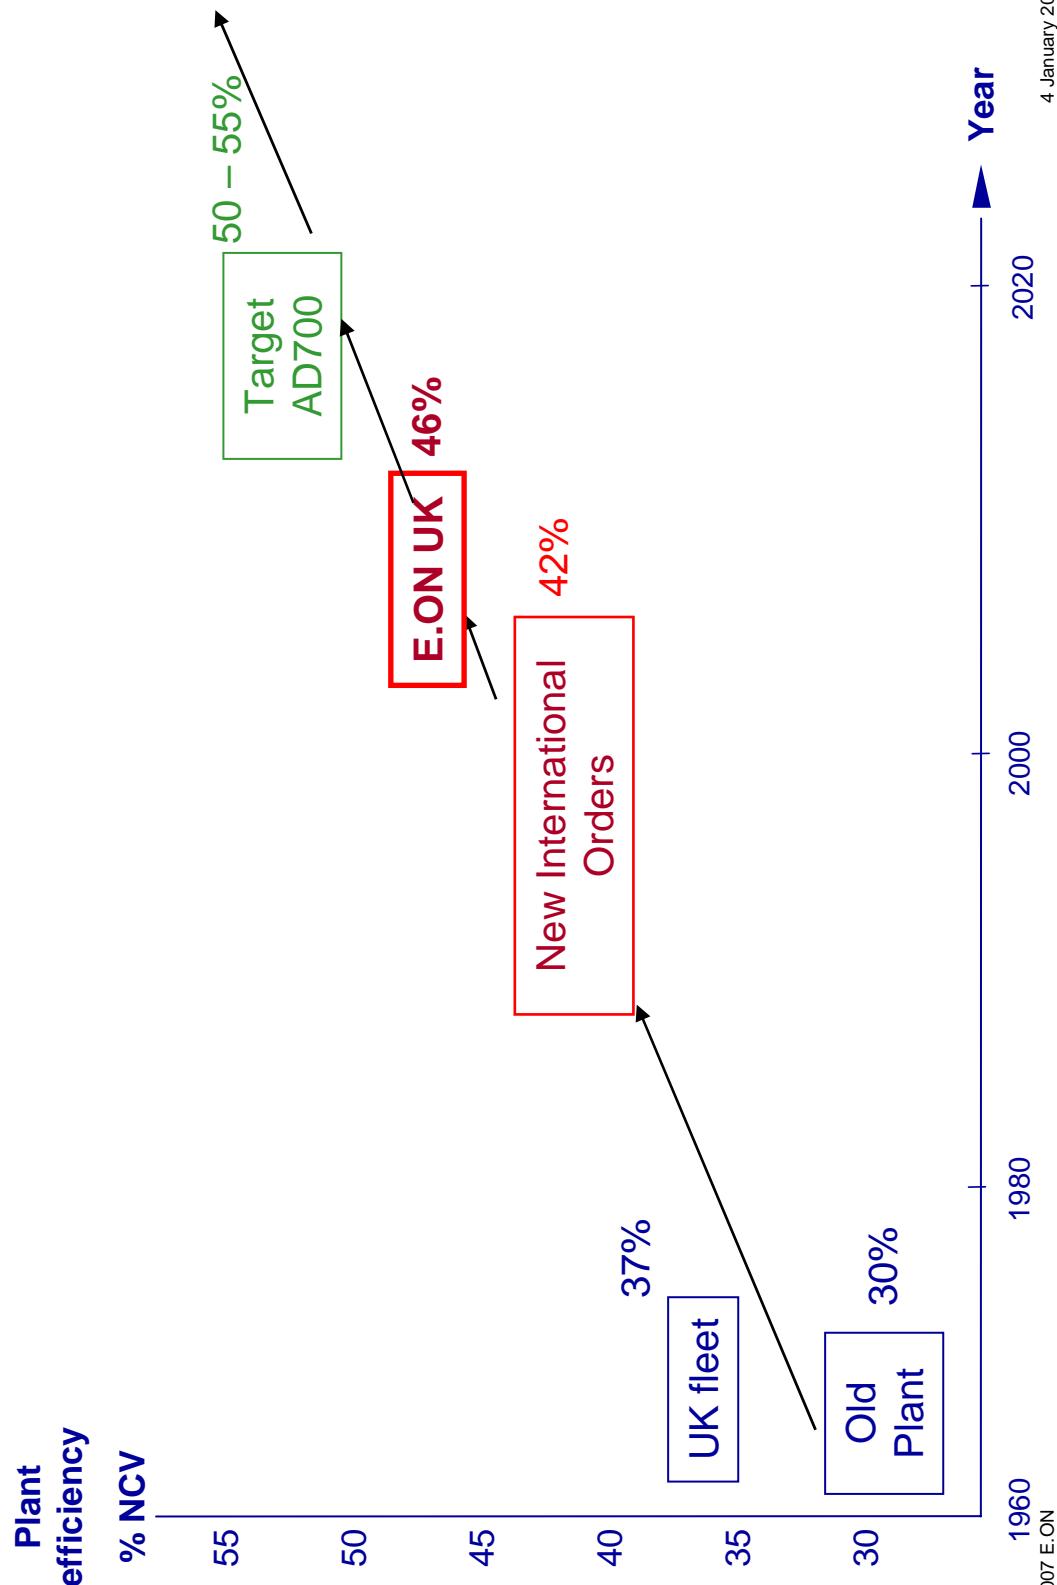

## Carbon dioxide abatement from fossil fuels

Twin track Approach:

- Track 1
  - Fuel switch
  - Biomass
  - Efficiency improvements
- Track 2
  - Carbon Capture and Storage Technology

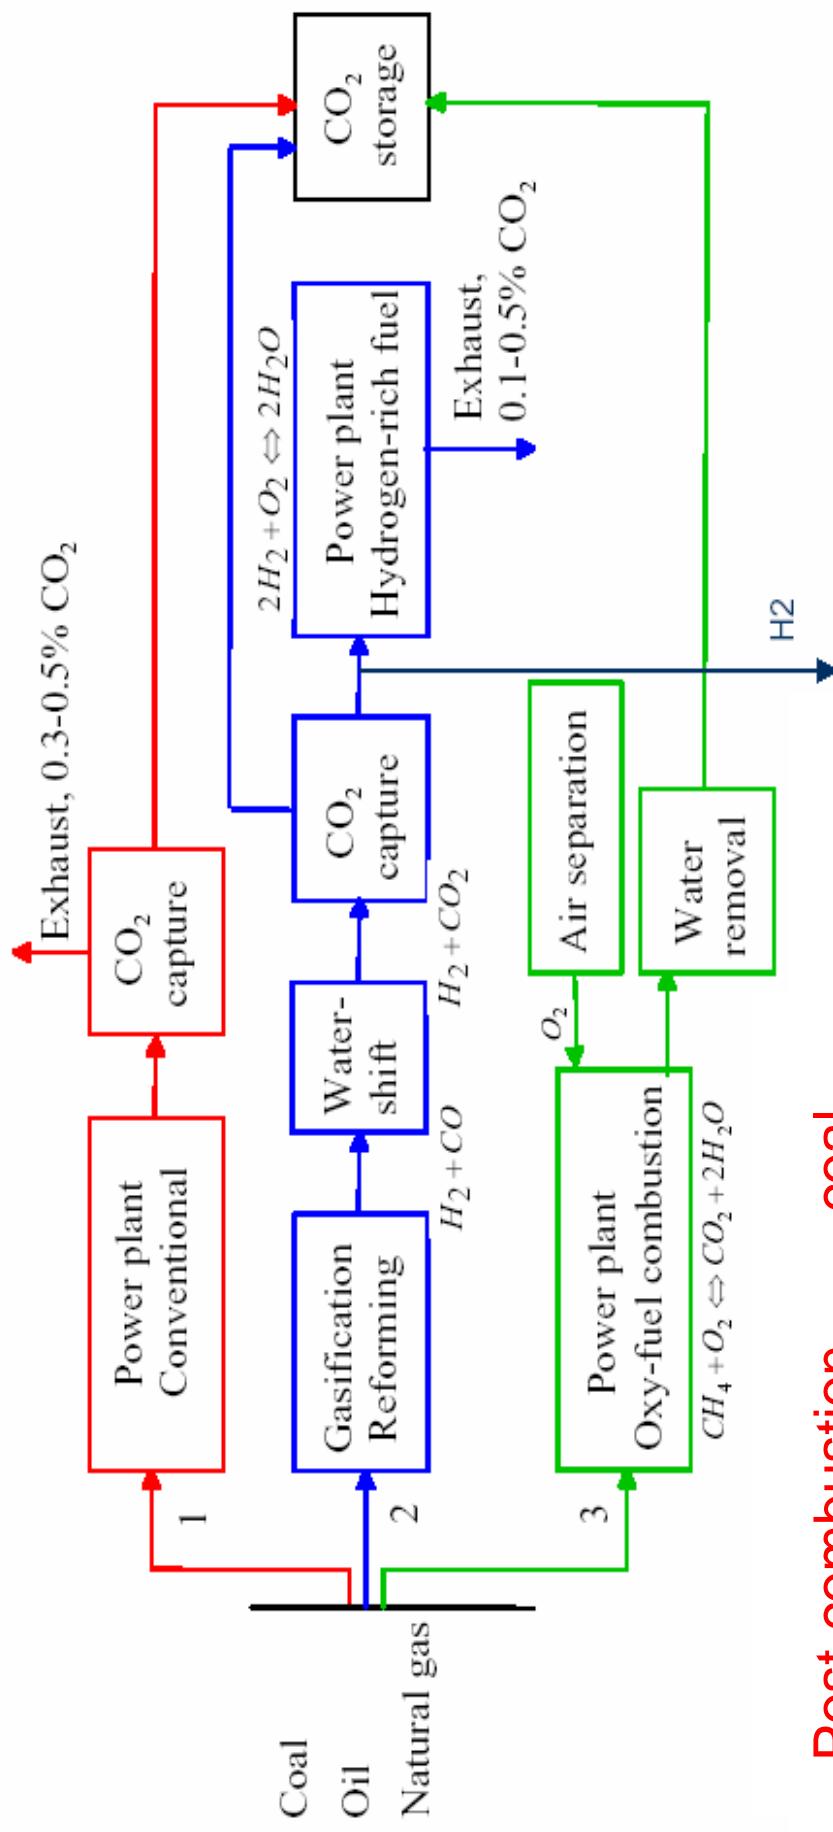

## Track 1: Efficiency Improvement - Coal fired plant

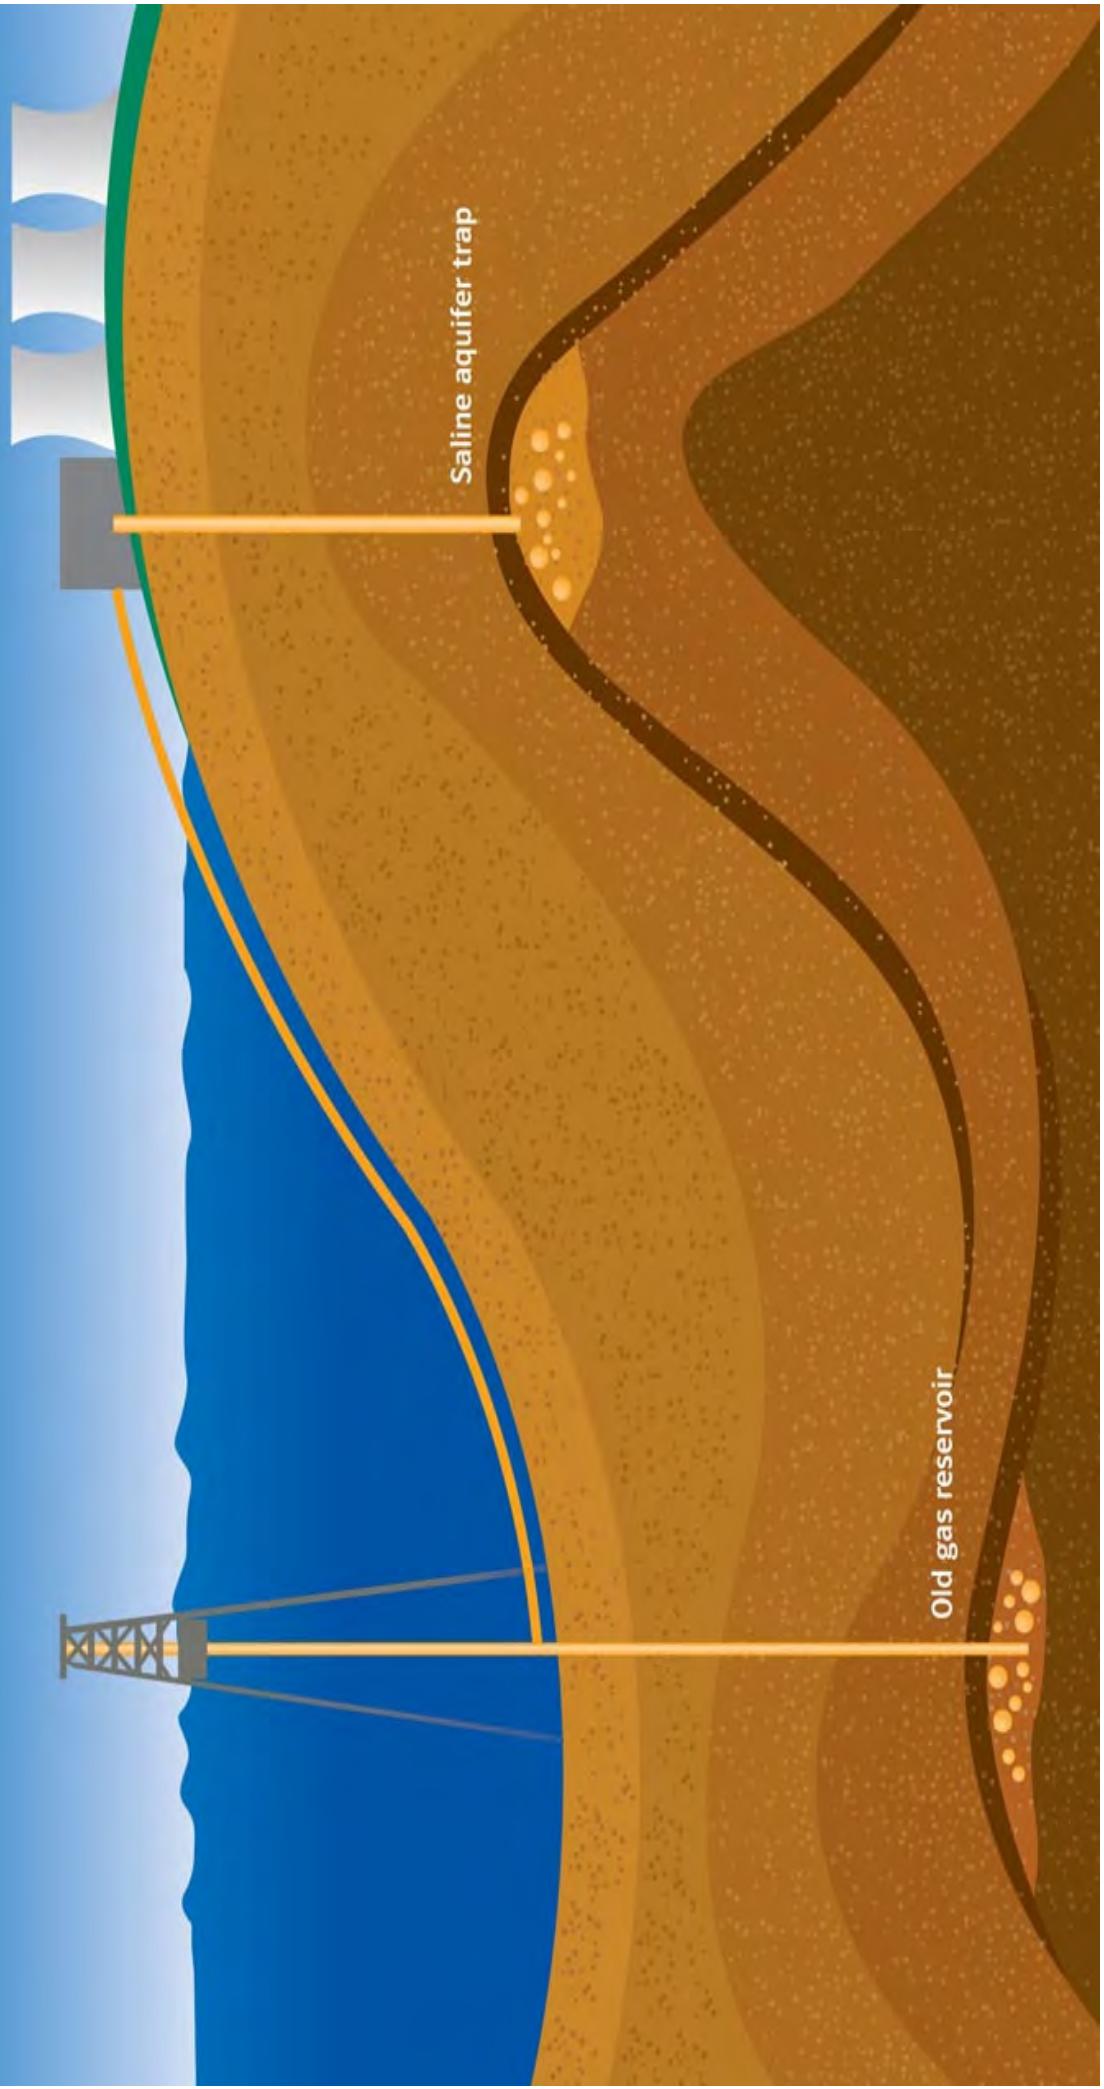

## Kingsnorth 5 & 6 – Artist's Impression (expected ~2013)

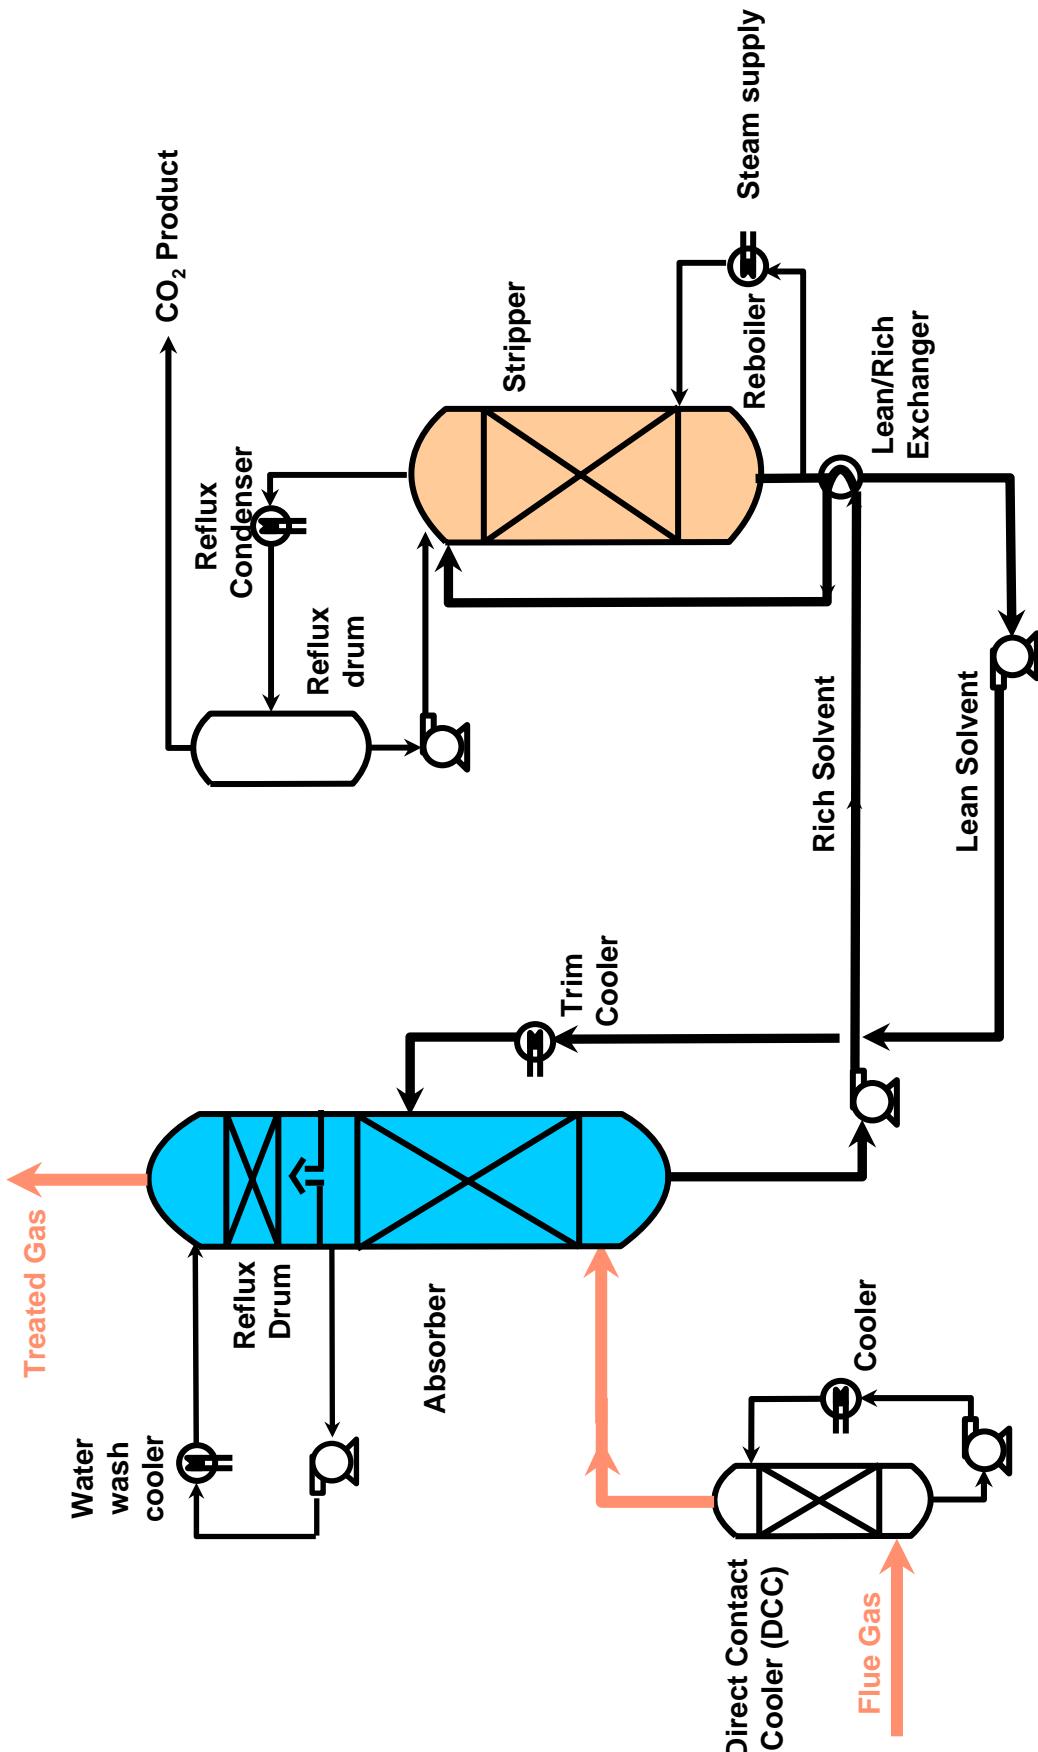

## Track 2: Options for power plant CO<sub>2</sub> capture

1. **Post-combustion** – coal
2. **Pre-combustion** – coal, natural gas
3. **Oxy-fuel** – coal

## Amine Scrubbing for CO<sub>2</sub> Capture

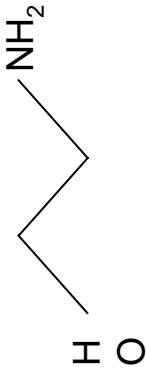

## Process Chemistry

- Primary and secondary amines react directly with  $\text{CO}_2$

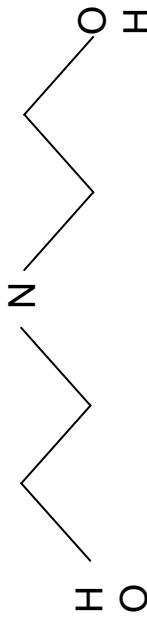

then,  $\text{R}_1\text{R}_2\text{NCOO}^- + \text{H}_2\text{O} \leftrightarrow \text{R}_1\text{R}_2\text{NH} + \text{HCO}_3^-$  [but  $K \ll 1$ ]

- Monoethanolamine (MEA) – primary amine

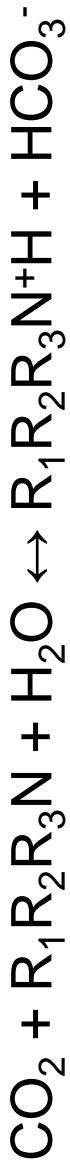

- Diethanolamine (DEA) – secondary amine

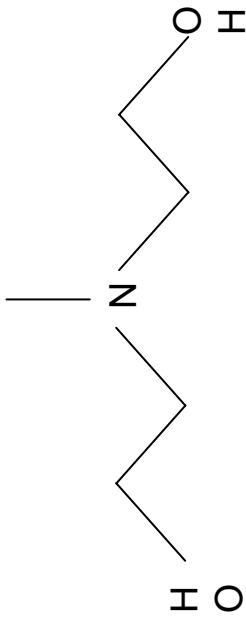

## Process Chemistry

- Tertiary amines react indirectly with CO<sub>2</sub>
- Base catalysed hydrolysis of CO<sub>2</sub>

- Methyl diethanolamine (MDEA) – tertiary amine

## Process Chemistry

- Reaction rate and reaction enthalpy for common amines

	Reaction rate	Reaction Enthalpy kJ/mol	Stoichiometry
Ammonia concentr.			mol/mol
MEA	~ 7000	90	0.5
DEA	~ 1000	80	0.5
AMP	~ 700	75	1
MDEA	~ 7	60	1

## Amine scrubbing advantages and disadvantages

- Advantages
  - 70+ years of experience with industrial gas streams
  - Retro-fit to existing and new conventional plant
  - Bypass
    - Pure CO<sub>2</sub> stream for storage
    - One of most developed CO<sub>2</sub> capture options (1000te/day)
- Challenges
  - High energy penalty (~10% points)
  - High cost - capital and operating
  - Footprint
  - Scale-up (13,000te/day)
  - Corrosion & degradation (SO<sub>2</sub>, O<sub>2</sub>, particulate, etc)

## Development activities

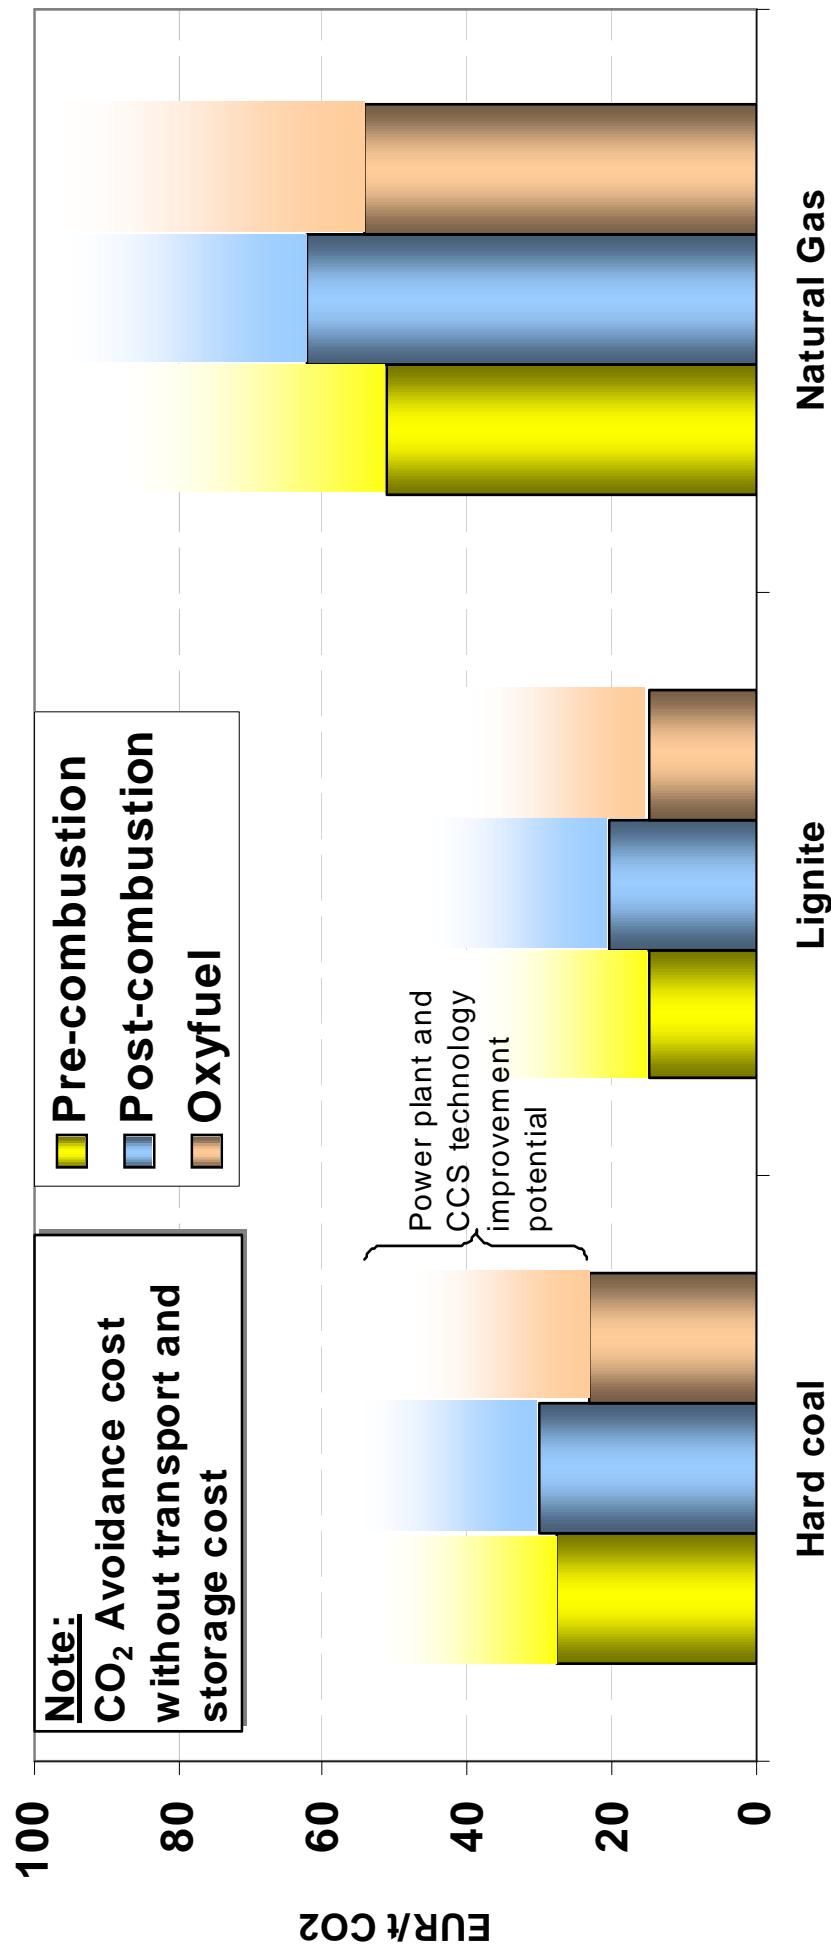

- Issues to address
- Cost and energy penalty – advanced amines/reagent and engineering
  - Power plant integration – gas path and heat/steam
  - Corrosion – new materials
  - Degradation – flue gas pre-treatment
  - Scale-up – build & operate pilot, demo, full scale plants
- E.ON UK activities
  - CASTOR EU project – [www.co2castor.com](http://www.co2castor.com)
  - International Test Centre (ITC) sponsor – [www.co2research.ca](http://www.co2research.ca)
  - CAPRICE EU/Global project – [www.caprice-project.eu](http://www.caprice-project.eu)
  - Ammonia process demonstration – E.ON Nordic/Alstom
  - 6te/day CO<sub>2</sub> pilot plant - E.ON Benelux
  - Others...

## Conclusions – Amine scrubbing of CO<sub>2</sub>

- Ongoing requirement for fossil fuel fired power plant
  - Cleaner fossil fuel plant technically feasible
- Two track approach to reducing CO<sub>2</sub> emissions
  - Track 1: Efficiency, fuel selection (35% reduction)
  - Track 2: Carbon capture and storage (90-95% reduction)
- Amine scrubbing is a leading capture option, but needs
  - Amine chemistry development
  - Engineering development
  - Scale-up
  - Integration into power plant
- Leading technologies at similar stage of development and demonstration
  - Uncertainty over cost of carbon capture technologies
  - Uncertainty over future value/cost of carbon credits

## Comparison of Costs Associated with CO<sub>2</sub> Capture Technologies

# Introduction

## Why adsorption?

The University of  
Nottingham  
*Nottingham Fuel  
& Energy Centre*

- The CO<sub>2</sub> capture step is projected to account for 75 % for the overall carbon capture and storage process.
  - Post-combustion
    - Aqueous solutions of amines used by industry as adsorbents for acid gas (chemical solvents) and all commercial CO<sub>2</sub> capture plants use similar processes
    - Technologies require significant modification, ultimately leading to high capital and running costs
    - Typical energy penalty incurred by an MEA plant estimated 15 – 37 % of net output of plant (Herzog and Drake 1993)
  - Pre-combustion
    - Use of physical absorption (ie Rectisol and Selexol)
    - Current physical absorption systems (eg. Selexol) large efficiency loss ca. 6% due to compressing the resultant CO<sub>2</sub>.
  - Need for the development of alternative low cost technologies to provide a more effective route for the capture and storage of CO<sub>2</sub> on a global scale.

# Summary of Adsorption Research

- Post-combustion capture
  - The Partial Removal of CO<sub>2</sub> from Flue Gases using Tailored Coal-Derived Carbons BCURA; Project B65 (2002-05)
  - Developing effective adsorbent technology for the capture of CO<sub>2</sub> in fossil fuel fired power plant. Carbon Trust; 2002-6-38-1-1 (2003-07)
  - Assessment of Options for CO<sub>2</sub> Capture and Geological Sequestration. RFCSS; RFC-CR-03008 (2003-07)
  - Developing effective adsorbent technology for the capture of CO<sub>2</sub>. EPSRC Advanced Research Fellowship, Dr T.C. Drage; EP/C543203/1 (2005-10)
- Pre-combustion capture

# Introduction

## Conditions for Capture

Nottingham Fuel  
& Energy Centre

As with solvent systems physical adsorption systems work for high pressure, whilst chemical amine systems are needed at atmospheric pressure

	Pre-combustion capture (after water gas shift) <sup>a</sup>	Post-combustion capture <sup>b</sup>
<b>Gas composition</b>		
CO <sub>2</sub>	35.5 %	15 – 16 %
H <sub>2</sub> O	0.2 %	5 – 7 %
H <sub>2</sub>	61.5 %	-
O <sub>2</sub>	-	3 – 4 %
CO	1.1 %	20 ppm
N <sub>2</sub>	0.25 %	70 – 75 %

# Post combustion capture the need for **chemical adsorbents**

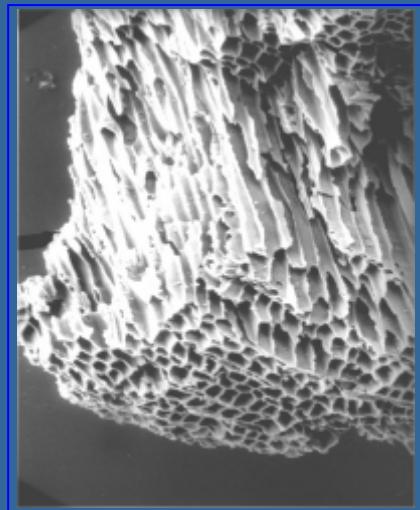

Nottingham Fuel  
& Energy Centre

## Supported-polyethylenimine

High N-content active  
Carbons(1,2)

## Amine-CO<sub>2</sub> chemical adsorption

(1) Drage, T.C., Arenillas, A., Smith, K., Pevida, C., Pippo, S., and Snape, C.E. (2007) Preparation of active carbons from the chemical activation of urea-formaldehyde and melamine-formaldehyde resins for the capture of carbon dioxide. *Fuel*, **86**, 22-31

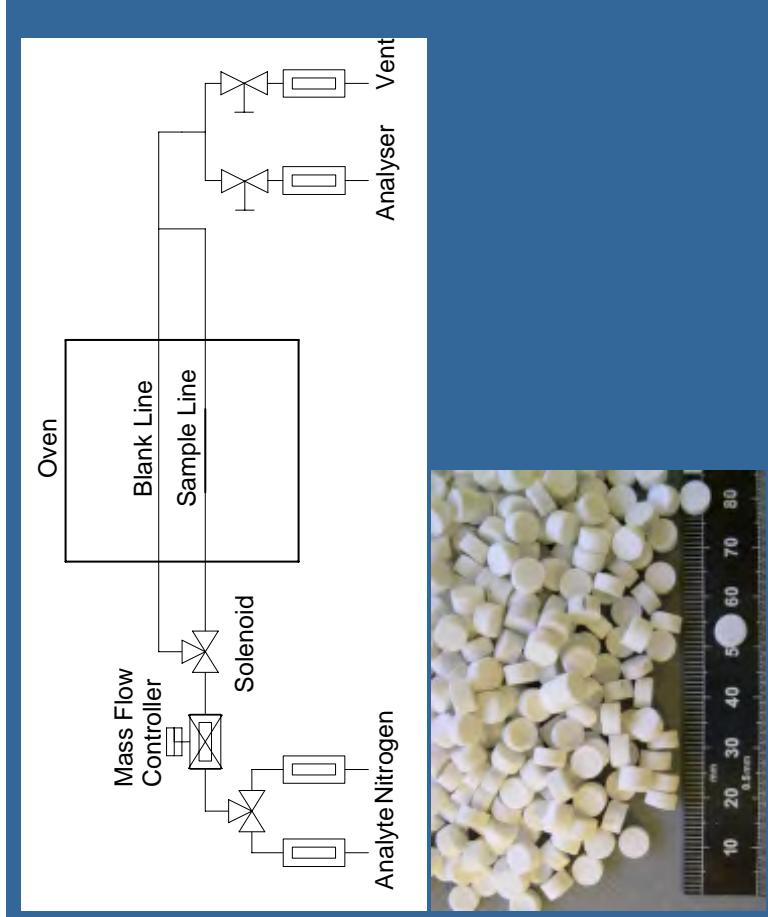

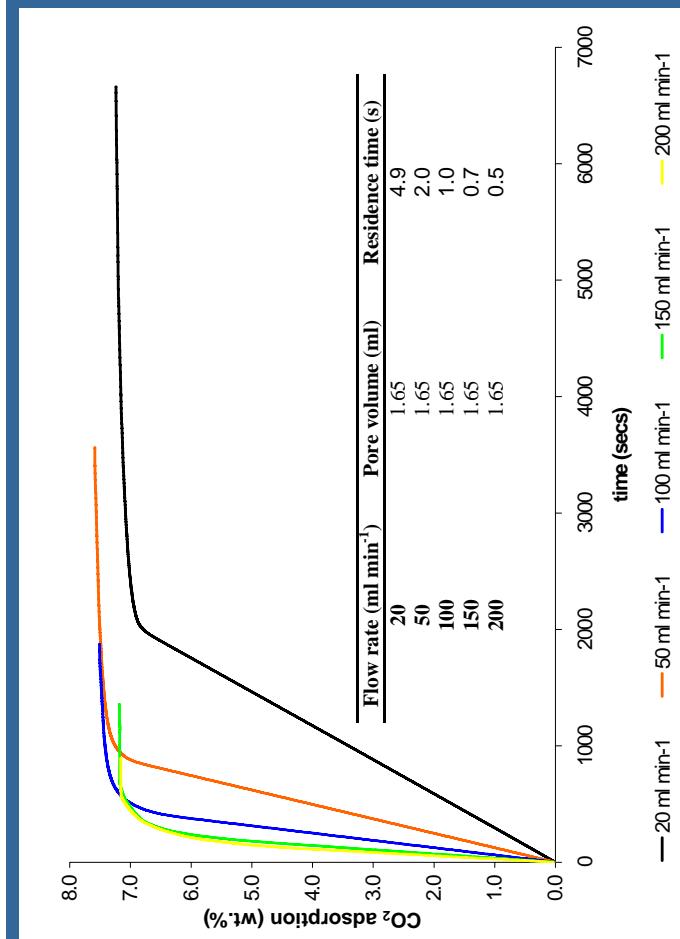

(2) Arenillas, A., Drage, T.C., Smith, K.M., and Snape C.E. (2005). CO<sub>2</sub> removal of carbons prepared by co-pyrolysis of sugar and nitrogen containing compounds. *Journal of Analytical and Applied Pyrolysis*, **74**, 298-306.

# Adsorbent Capacities

## Silica-PET adsorbents

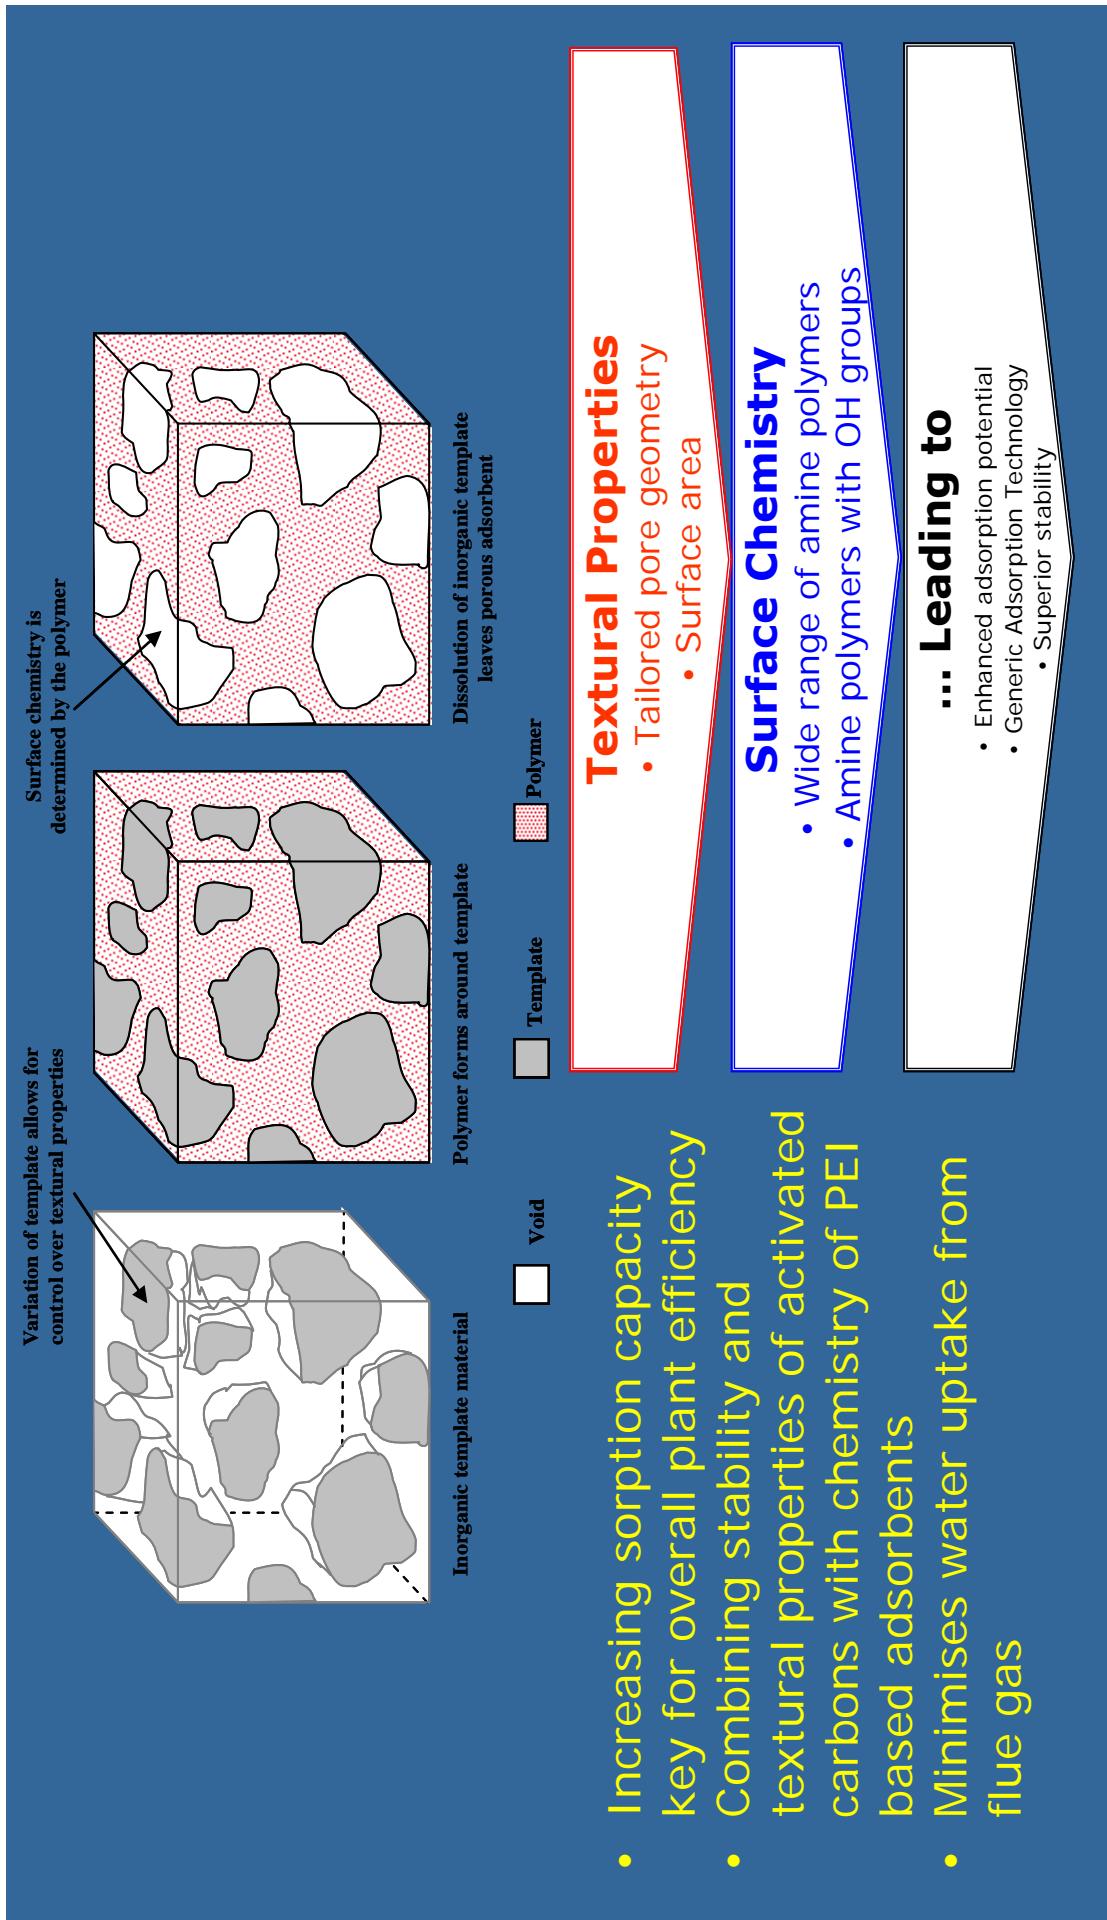

Nottingham Fuel  
& Energy Centre

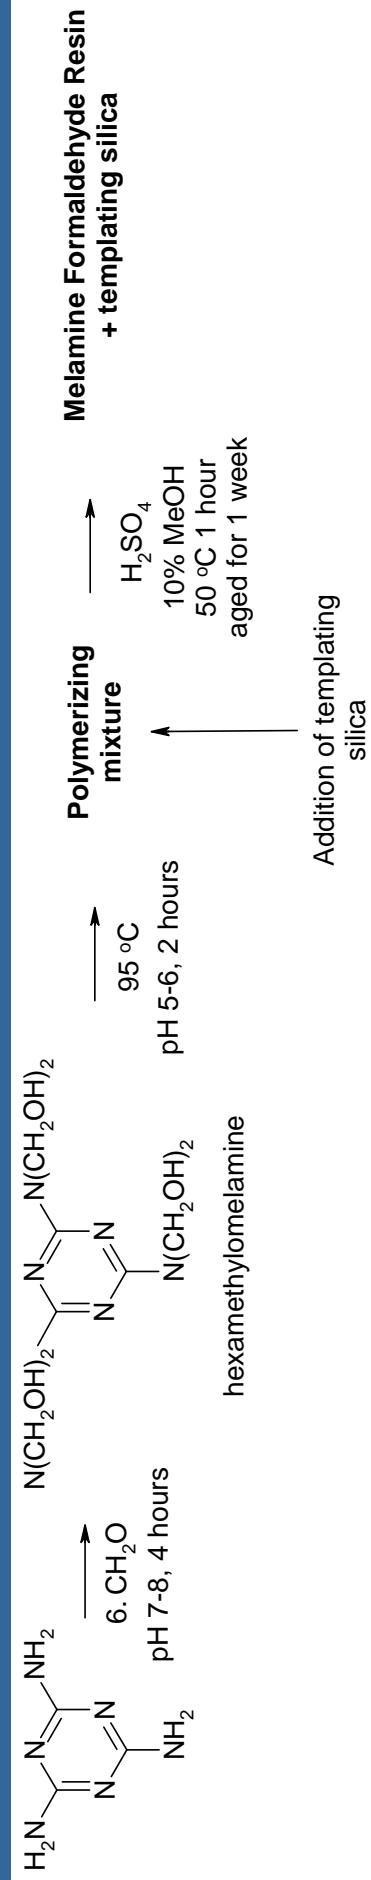

- Adsorption capacities explored under equilibrium and dynamic conditions using simulated flue gases
- Simulated flue gas conditions capable of adsorbing  $\text{CO}_2$  with high breakthrough capacities, requiring only short residence times
  - Potential demonstrated for selective regeneration of other acid gases, for example  $\text{SO}_2$

# Templated adsorbent synthesis

# Templated MF resin synthesis

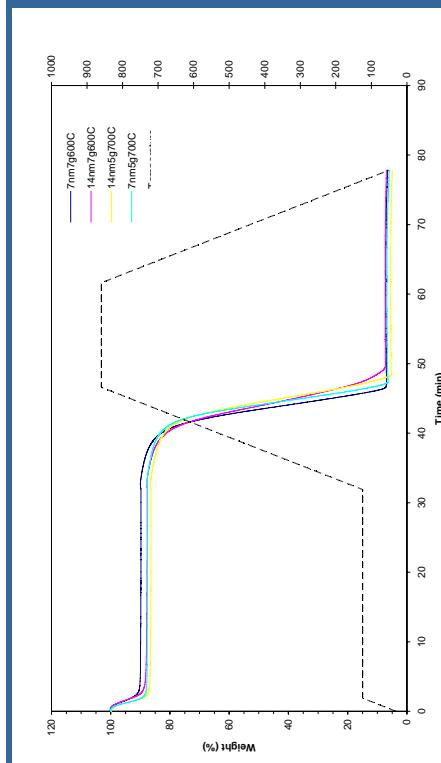

**Template** - two types of fumed silica used (with and without CTAB surfactant):  
7 nm  
14 nm

## Silica to melamine ratios used

1:1 (5g)  
1.4:1 (7g)

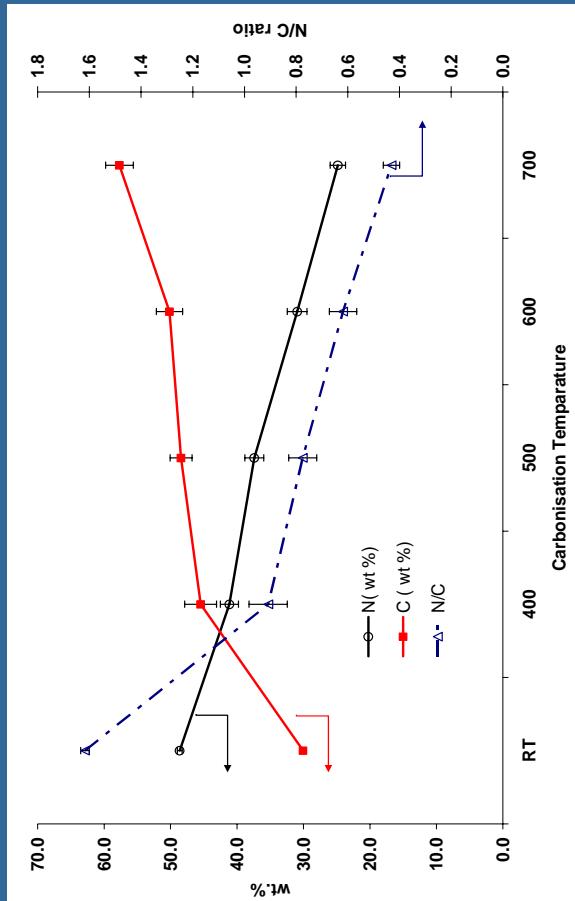

**Thermal treatment** – polymers analysed without heating and after  
Carbonisation at 400, 500, 600 and  $700^\circ\text{C}$   
**Template removal** - 10% NaOH solution

# Elemental Composition

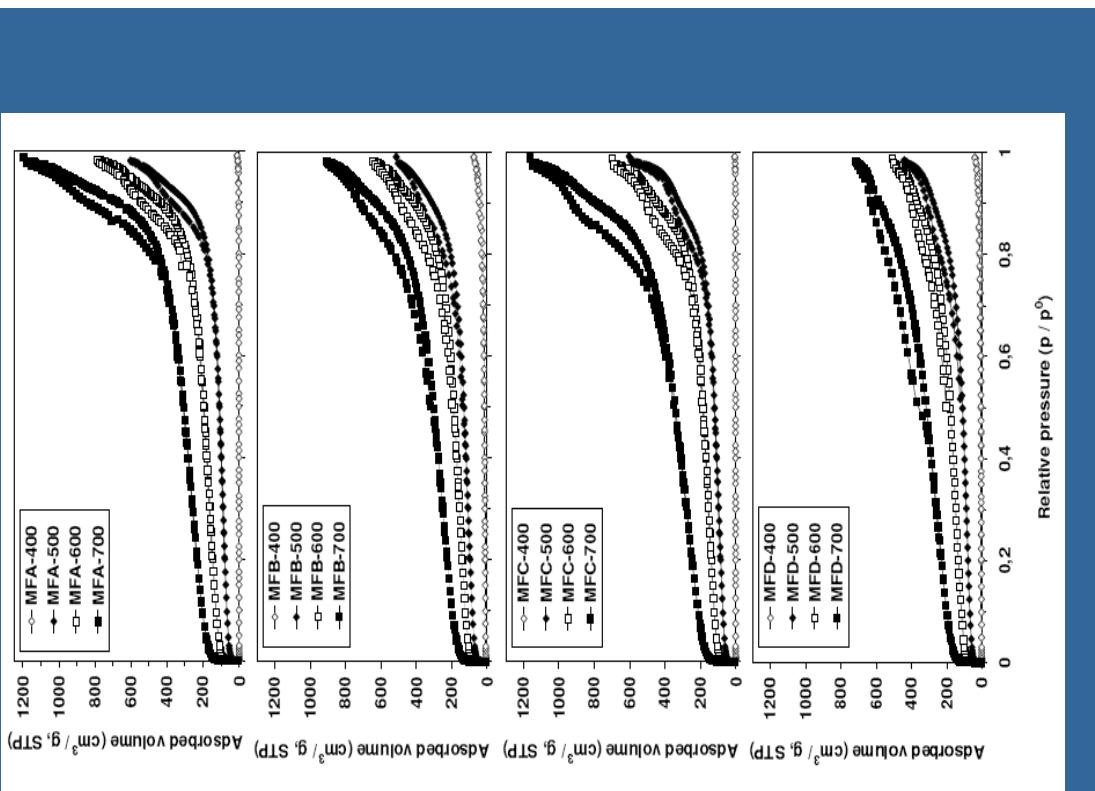

- Template Removal – Loss on ignition analysis used to confirm >90% removal of silica template
- Materials have high N content as expected for MF resin source
  - N and H decrease with carbonisation, concomitant increase in C

Carbonisation temperature	Sample	N (wt %)	C (wt %)	H (wt %)	N/C
RT	7nm5g	48.5	30.1	3.9	1.6
	7nm7g	48.8	30.0	3.7	1.6

		600	471	0.84
		700	800	0.99

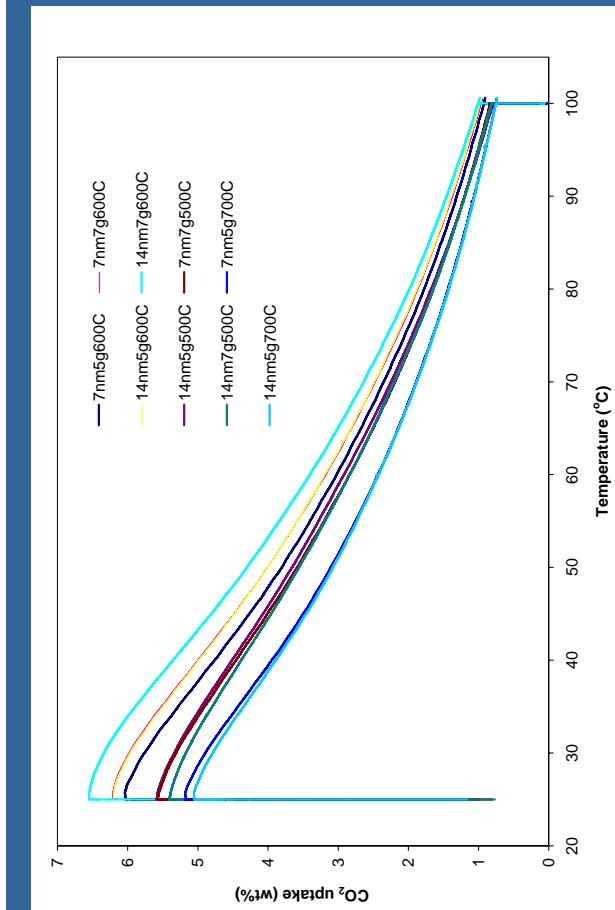

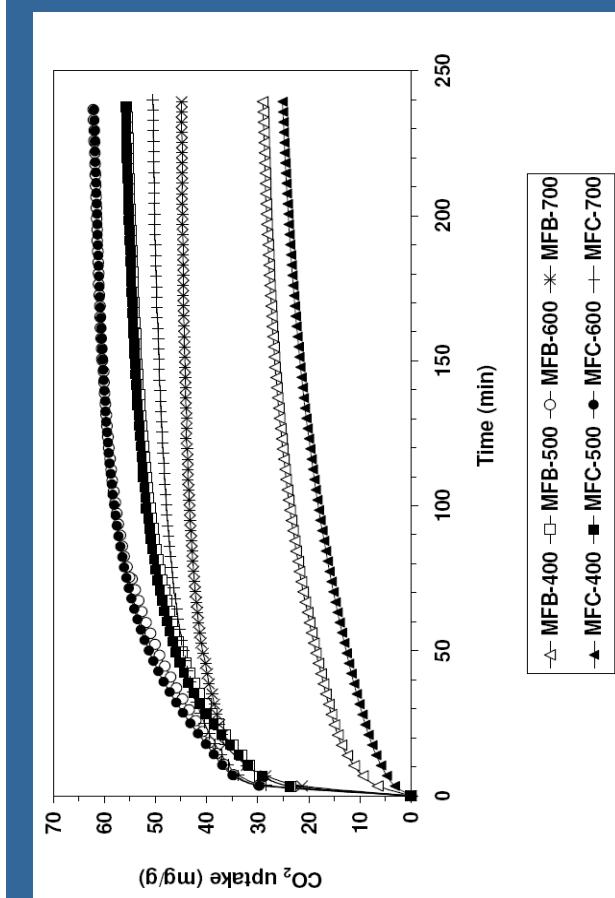

- Micro and mesoporosity developed
- Surface areas not developed for non-pyrolysed samples
  - Surface area and pore volume increases with carbonisation temperature

# Adsorption Rate and Influence of temperature

Nottingham Fuel  
& Energy Centre

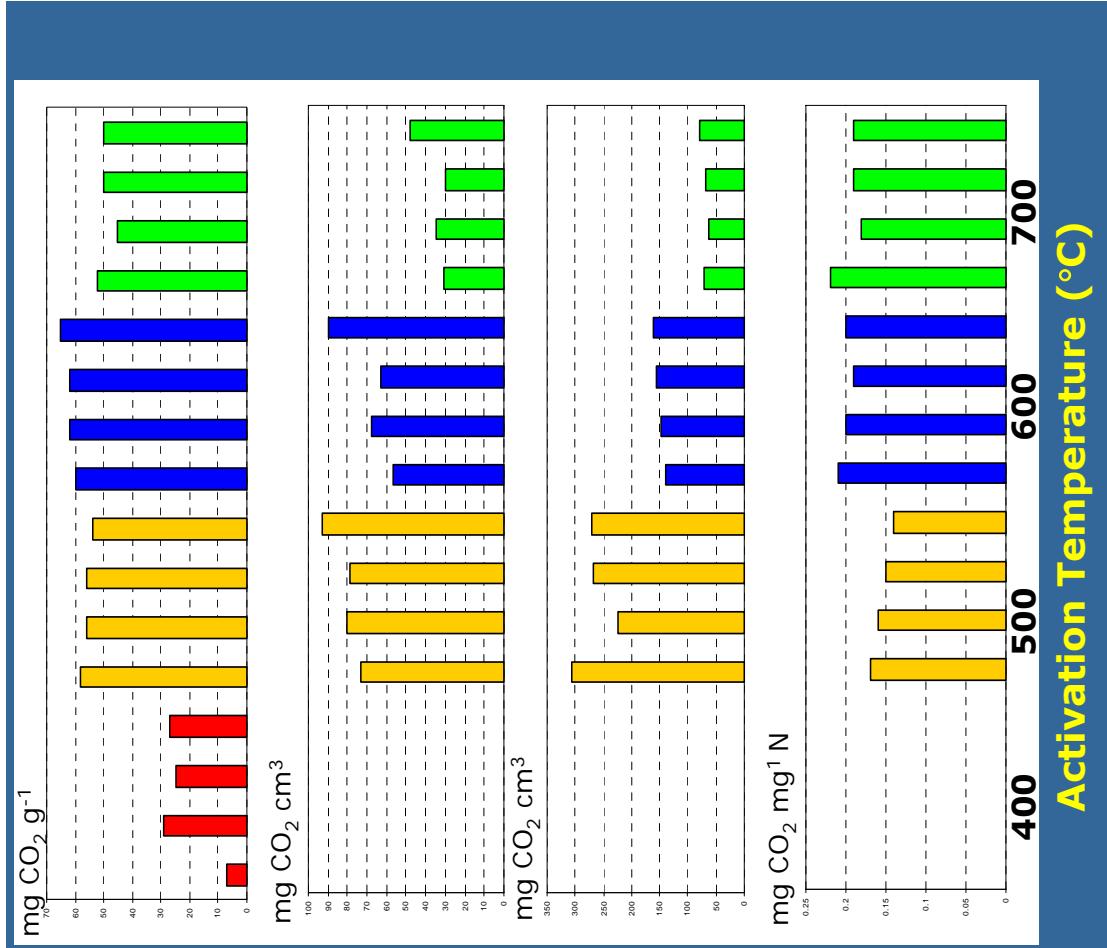

- Rate of adsorption varies for different activation temperatures – adsorption rate fastest for 700 °C activation.
- Adsorption capacity decreases with temperature (25 – 100 °C, 100% CO<sub>2</sub>, 0.25 °C min<sup>-1</sup> ramp)
- Performance better than some physical adsorbents – especially at elevated temperatures.

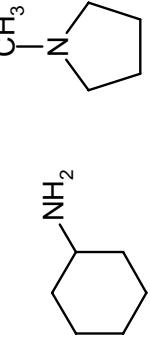

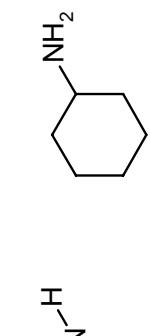

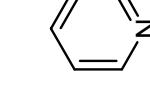

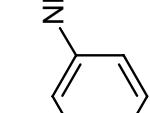

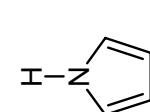

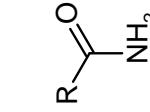

# Adsorption Results

## What controls capacity?

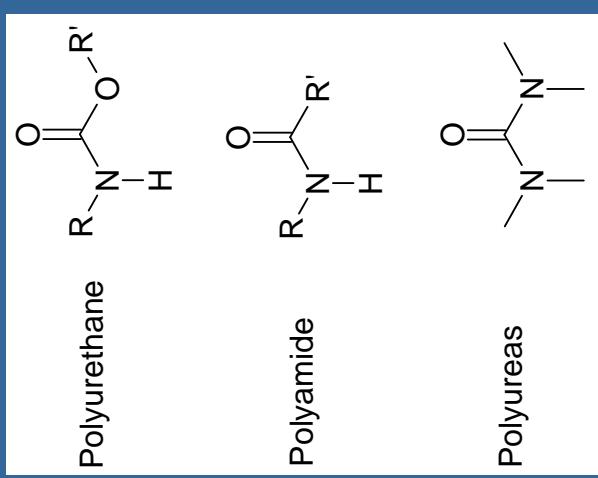

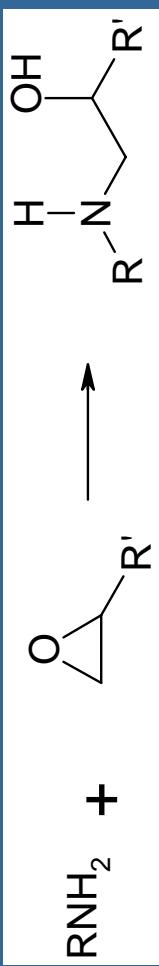

- **Overall adsorption capacities**
  - Highest from carbonisation at 600 °C
  - Independent of template
- **Normalised to  $V_p$** 
  - Activity decreases with activation temperature
  - Pore volumes greatest for 700 °C
  - Capacity controlled by both textural and chemical properties
- **Normalised to  $V_p - V_{MESO}$** 
  - Further evidence for chemical influence
    - Negative relationship with micropore volume not expected
- **Normalised to N content**
  - Nitrogen content not key control on capacity
    - Nitrogen functionality altered by activation – higher temperature reduces basicity (XPS underway)
- **Adsorption a compromise between textural and chemical properties.**

# Problem with $pK_a$ polymer types

Compound						
$pK_a$	11.0	10.7	10.7	9.3	5.3	4.6

- From results it is clear that the presence of nitrogen alone is insufficient and that more basic nitrogen is required
  - Nitrogen within melamine-formaldehyde resin has a low  $pK_a$  as a result of adjacent functional groups.
  - Most common nitrogen containing polymers are linked via an amide group
  - One possible solution is epoxy-resins
  - New polymer and synthesis methods being explored

# Adsorbent Regeneration

*Nottingham Fuel  
& Energy Centre*

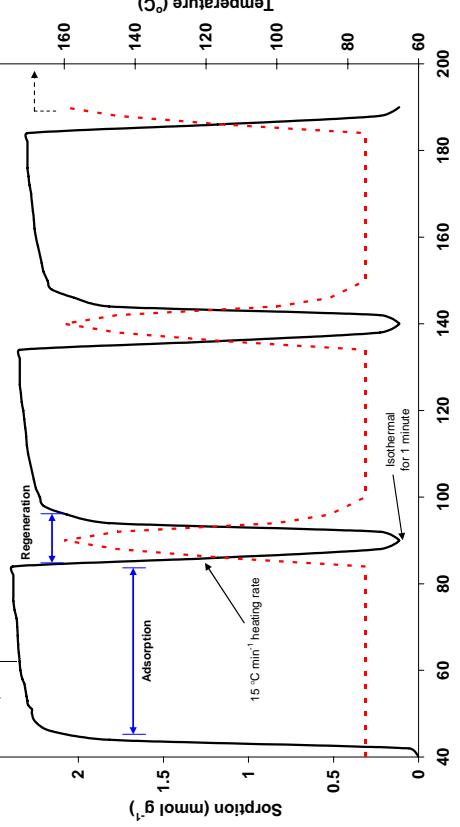

## **Efficient adsorbent regeneration is crucial**

- To be economic the adsorbents will have to be regenerable. Energy required for regeneration will dictate the efficiency and economics of the process. Minimising temperature differential between adsorption / desorption cycles and stripping gas volumes are key to efficient operation.
- Regeneration strategy will influence adsorbent lifetime and replacement rate.

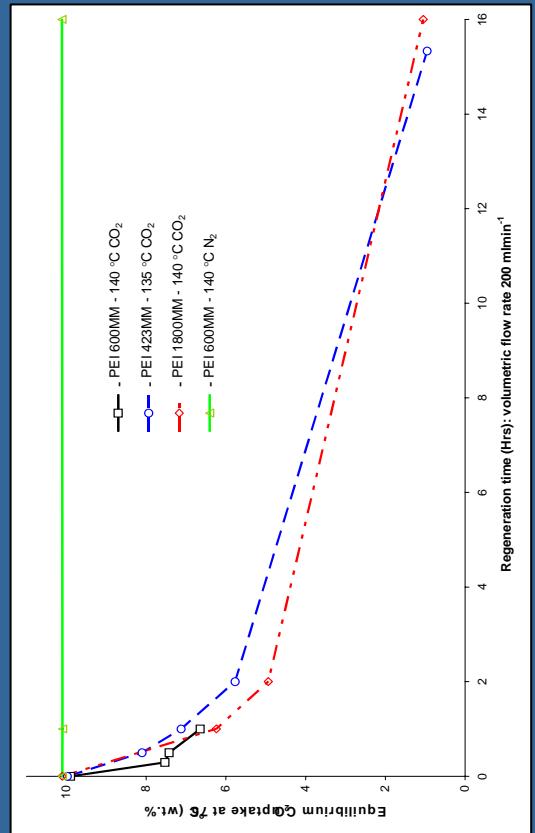

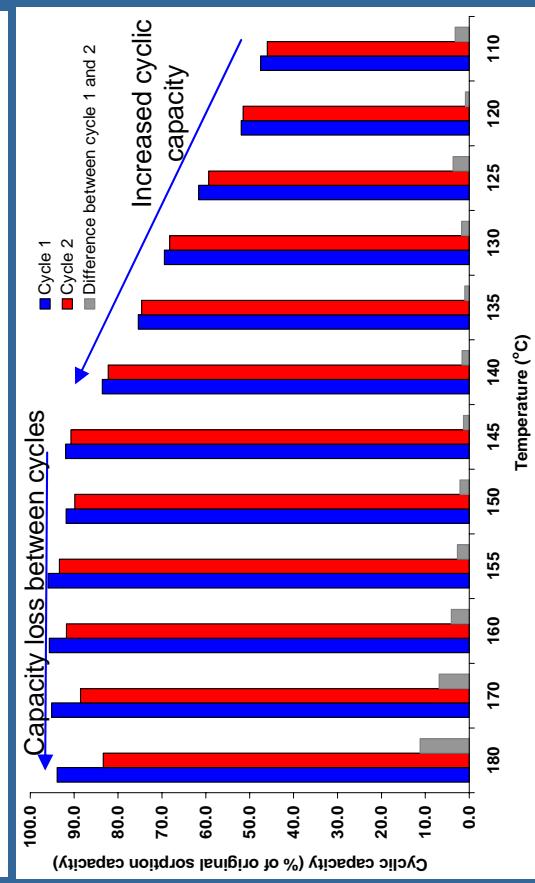

Two regeneration strategies tested to determine feasibility for scale-up:

- Thermal swing adsorption cycles over a range of time and temperatures in CO<sub>2</sub>
- Using nitrogen as a stripping gas at elevated temperatures.

# Regeneration PEI based adsorbents - thermal

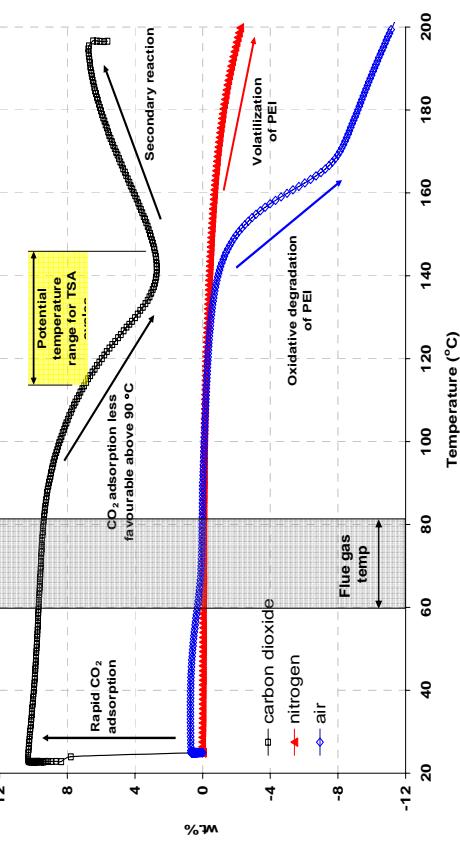

- Regeneration in a stream of pure  $\text{CO}_2$  by temperature swing
- Cyclic capacity dependent upon temperature
- > 90% of sorption capacity recovered on cycling
- Problems arise with secondary reaction leading to short adsorbent lifetime

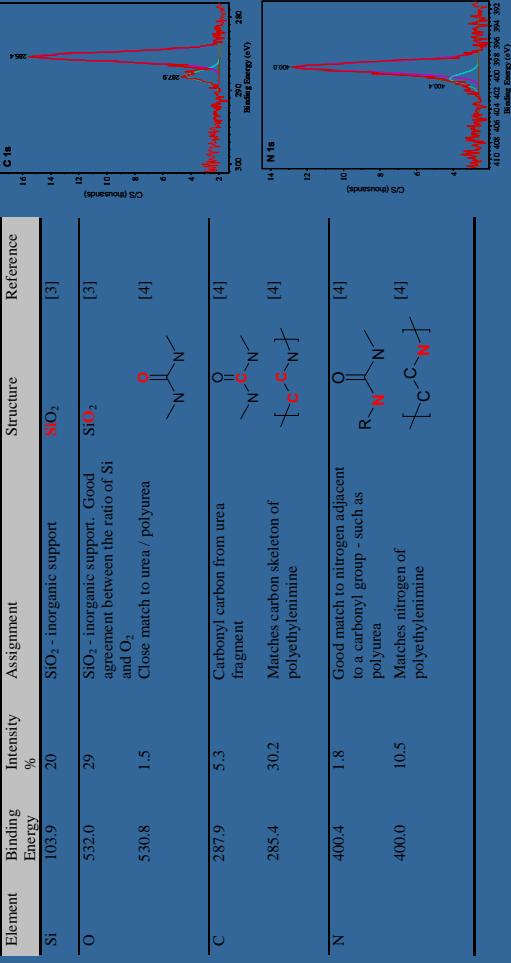

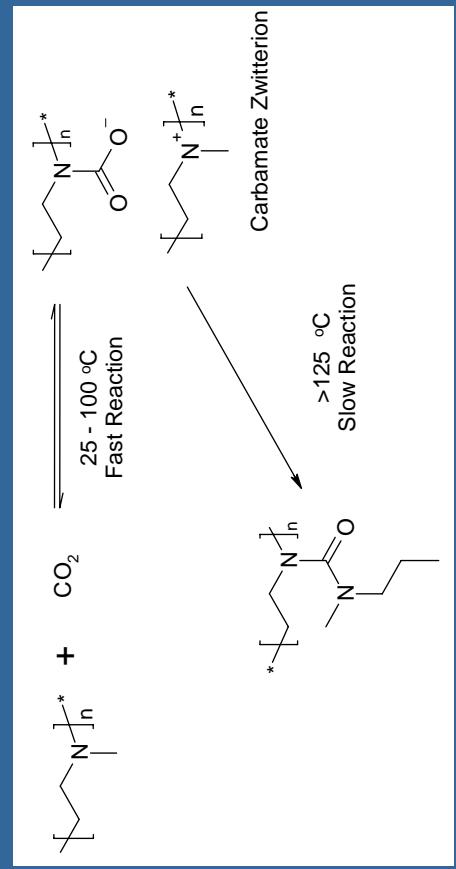

# Regeneration

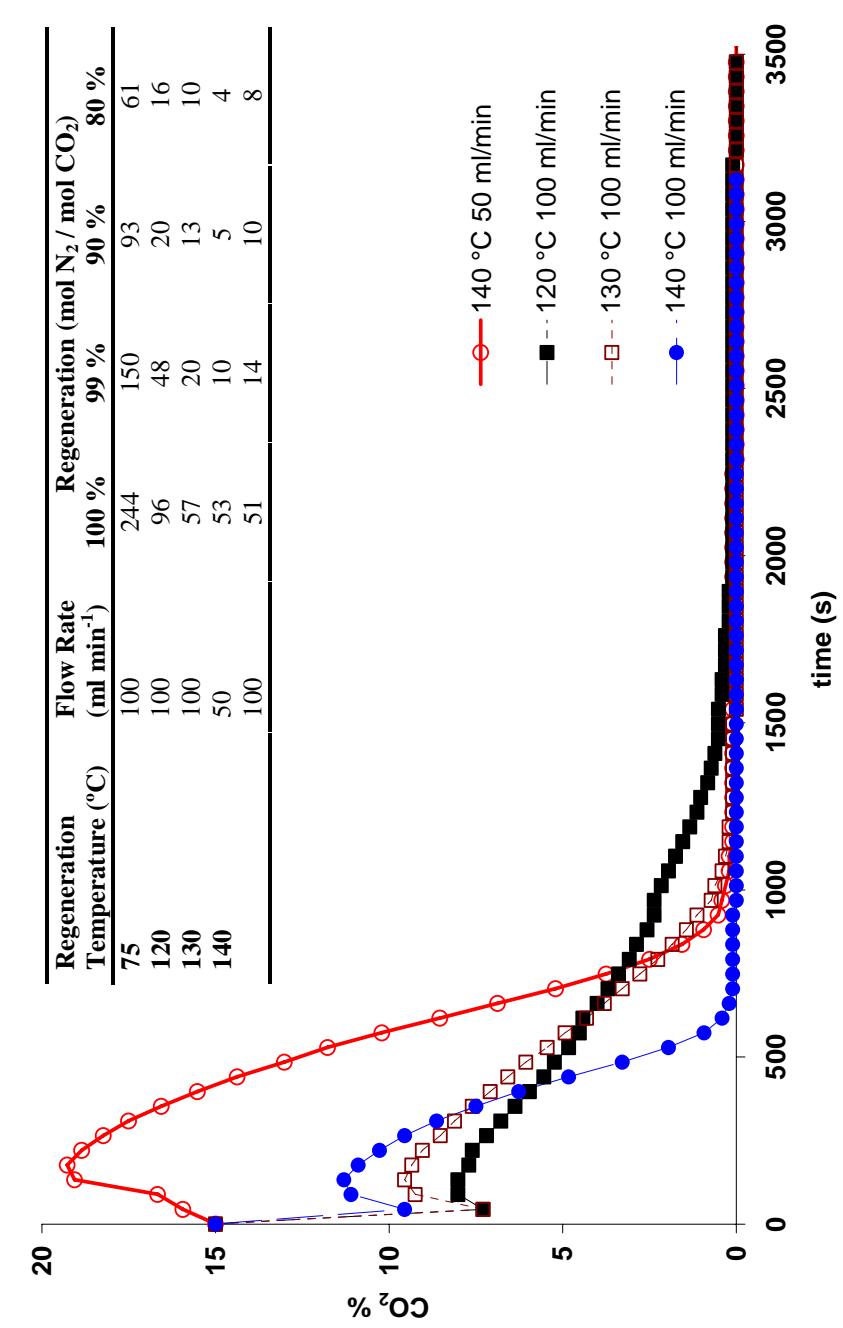

## Secondary reaction

- $^{13}\text{C}$  NMR, XPS, elemental analysis, DRIFT used to identify secondary reaction product
- Reaction proposed to result in the formation of a urea type linkage

# Regeneration Stripping gas

- Using nitrogen as stripping gas suggests potential for steam stripping as a method for sorbent regeneration

# Post-combustion capture economic studies

Economic study\* based on:

- 90 % CO<sub>2</sub> removal
- Pressure drop < 6 psi
- Use of enriched amine SBA-15 substrate
- Adsorption offers potential cost saving over MEA scrubber
- Fixed bed not viable due to large footprint
- Novel radial flow fixed bed reactor capable of providing best economic performance
- Nottingham investigating novel moving bed design

Table 1. Comparison of CO<sub>2</sub> Capture Unit Performance

	Flowrate per Unit (acfmin)	Absorber Units	Sorbent Mass (tonnes)	ΔP (psi)	Total Footprint (ft <sup>2</sup> )
MEA Scrubber	250,000	8-10	N/A	3-6	9,000
Fixed Bed	50,000	96	1,500	6	86,000
Fluidized Bed	150,000	8	1,100	0.3	7,000
Novel Fixed Bed					
Case 5	150,000	8	3,500	2.2	7,400
Case 11	300,000	4	1,300	2.9	9,700

Table 2. Plant Performance and Economics with CO<sub>2</sub> Capture

	ID Fan Load (MW)	Solvent Pump (MW)	Gross Plant Size (MW)	COE (c/kWh)	COE Increase
MEA Scrubber	22	3	491	7.56	55%
Fixed Bed	25	N/A	483	6.39	31%
Fluidized Bed	6.5	N/A	465	6.88	41%
Novel Fixed Bed					
Case 5	16	N/A	474	6.93	42%
Case 11	19	N/A	478	6.34	30%

# Pre-Combustion Capture

## Surface chemistry or textural?

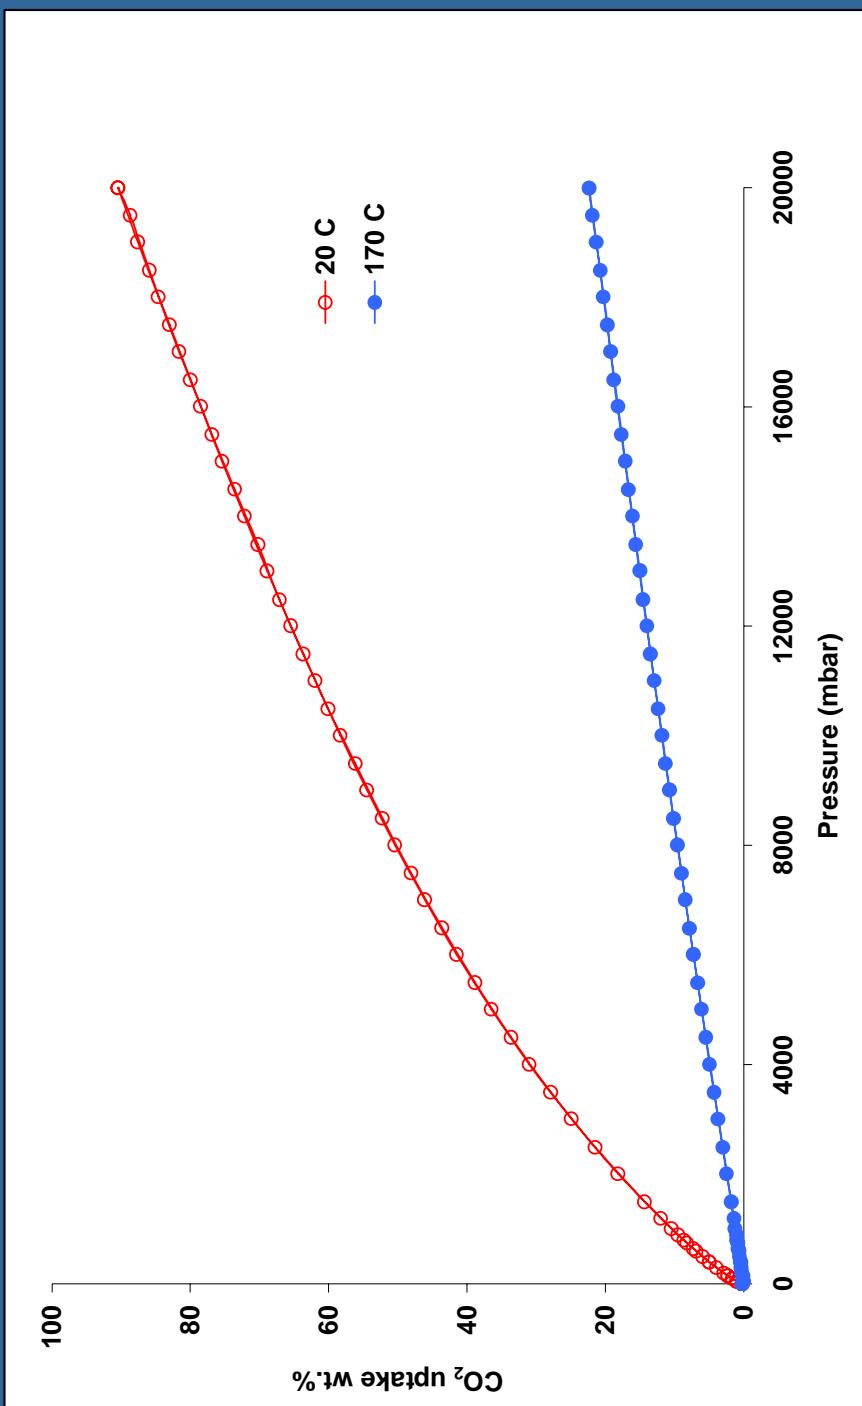

*Nottingham Fuel  
& Energy Centre*

- High pressure adsorption explored as a method for pre-combustion capture
- MF derived carbons activated at 700 °C have excellent performance, different trend compared to polyphenol derived ACs
- Enhanced performance at lower SA may increase volumetric capacity
- Different isotherm shape – potentially useful for other applications

# **CO<sub>2</sub> uptake**

## **IGA – AC3000**

- IGA allows thermal swing regeneration to be performed
- Activated PAN – high adsorption capacity
- Large potential for thermal swing regeneration

# Pre-combustion economics

- Based on a conservative adsorption capacity of 12 wt. %
  - Basic economic costing using fixed bed adsorption with pressure swing regeneration has potential economic benefits over current physical solvent systems
  - More detailed analysis of adsorption capacity under dynamic conditions required
- Advantage of adsorbents is the ability to produce CO<sub>2</sub> at relatively high pressure, even a pressure of 10 bar would have a significant impact in reducing CO<sub>2</sub> compressor cost and power requirements (100 bar for transportation)
  - Moreover, if higher (20+ %) adsorption capacities can be achieved, TSA cycles can potentially be employed leading to significant benefits as CO<sub>2</sub> can be recovered at 30 – 40 bar.
  - System has the potential to become a viable alternative in the future for bulk CO<sub>2</sub> removal

# Conclusions

- Range of successful adsorbents developed for both pre and post-combustion capture
- Both techniques maximising adsorption capacity key to decrease amount of adsorbent required and regeneration time
- Regeneration of post-combustion capture more complicated due to the chemical nature of the adsorbents
- Pre-combustion capture has great potential if TSA can be used for regeneration of adsorbents and the production of pure CO<sub>2</sub> at high pressure
- Both pre and post-combustion capture offer potential economic and efficiency benefits over current solvent systems
