Columbia agar solution preparation

Gram-positive and Gram-negative bacteria were cultured on Columbia agar. 1 Litre of Columbia agar was prepared as follows; Columbia agar (41 g) was dissolved by boiling in distilled water (1 l). The solution was then autoclaved at 116 °C for 10 min. and left to cool at 50 °C.

Media preparation

The substrates to be tested were initially dissolved in DMSO or distilled water to give solutions of 10 mg/ml. The substrate solutions were incorporated into Columbia agar solution (200 ml) and added to sterile plates to give final concentrations of 50 mg/l. Columbia agar alone was used as a growth control. Solidified plates were surface dried in a warm air cabinet for 5 min.

Bacterial suspension preparation

Bacterial strains were obtained from the National Collection of Type Cultures (NCTC), Colindale, U.K., the American Type Culture Collection (ATCC), Cockeysville, U.S.A., or were isolated from clinical samples (wild strains) at the Microbiology Department of the Freeman Hospital, Newcastle-upon-Tyne, U.K.

McFarland tubes were labelled with numbers corresponding to the bacterial code on the plates. Sterile distilled water (2 ml) was added to each tube. Each bacterium was inoculated into the tube using a sterile loop. A densitometer was used to adjust the turbidity to 0.5 McFarland units ($1.5 \times 10^8$ organisms/ml).

Each bacterial suspension (200 μl) was pipetted into the corresponding tubes of a multipoint inoculator. Each set of plates received 1 μl of bacterial suspension, giving $1.5 \times 10^8$ organisms per spot on each inoculation. Twenty strains were inoculated per plate and the plates were incubated for 24 and 48 hours at 30 °C, and 24 and 48 hours at 37 °C.

Activity determination

The activity of the test substrates was determined by the development of red, pink, purple or orange colonies after incubation. The control plate was first taken for each substrate tested and examined for growth and colour. Each test plate was then compared to the control and the presence of red, pink, purple or orange colour was considered as positive evidence for the hydrolysis of the substrate by alanyl aminopeptidase; no colour or a pale yellow was considered as negative.
