\(^a\)The reaction was carried out on a 1 mmol scale at 0 °C. \(^b\)Unless indicated otherwise, the catalyst metals were charged in 10 mol % with 20 mol % (monodentate), 10 mol % (bidentate) ligand or 30 mol % TMEDA. \(^c\)Isolated yield. \(^d\)8 mol% FeCl\(_3\) / 20 mol% TMEDA. \(^e\)1 atm. \(^f\)Using THF/NMP (10:1) as a solvent. \(^i\)the reaction was carried at room temperature.
2.2 Discussion
As seen in Table S3, the Pd or Ni-catalyzed reactions gave rather low or no yields of cross-coupling products (entries 1 and 2), indicating a significant synergetic effect between iron and titanium. While the simple phosphine ligands (PBu$_3$, PCy$_3$); bidentate phosphine ligand (dppp); N-containing phosphine ligand (dmadpp), NHC ligand and 2,2'-bipy can all improve cross-coupling, FeCl$_3$/TMEDA proved to be the most effective catalyst system, which promotes the oxidative cross-coupling reactions with yields up to 68% (entries 3–9). Also, we examined the influence of different titanates (entries 9–12). The cross-coupling occurred in a highly selective way (78% yield) by using easy preparation and handling of solid tbepc (entry 12). Fe(acac)$_3$ could also promote the cross coupling almost equally well, yet with prolonged reaction time (entry 13). Lowering the loading of the catalyst to 8 mol% FeCl$_3$/20 mol% TMEDA did not affect the yield (entry 14). Bearing in mind that atmospheric oxygen or oxygen is indeed the greenest candidate oxidant, we tried to use atmospheric oxygen or oxygen as an oxidant in this reaction (entries 15 and 16). It was observed that while dry air could give an acceptable yield (66%) with a prolonged reaction time, the reaction using oxygen could proceed as well as those using DCE. We also explored the influence of solvent and temperature. The results showed that using THF/NMP instead of THF as a solvent did not improve the yield (entry 17). Rising the reaction temperature shortened the reaction time, yet the yield of cross-coupling product was reduced (entry 18).

3. General experimental details
All NMR spectra were collected using 400 MHz (100 MHz for $^{13}$C spectroscopy) and all spectra recorded with tetramethylsilane as an internal standard unless otherwise noted. ESI mass spectra were recorded on TRACE MS spectrometer. High resolution mass spectra (HRMS) were obtained with a Bruker microTOF (ESI). Infrared data were acquired using an AVATAR 360 FT-IR spectrophotometer. Elemental analysis was carried out with an Elementar Vario instrument. Melting points were recorded on a TECH X-4 microscopic instrument and uncorrected.

4. General procedure for the additions of the mixed diaryl titanates to PhCHO
4.1 General remarks for the preparation of aryl Grignard reagents
All reagents and solvents used for aryl magnesium reagents and reactions were freshly dehydrated before use. The corresponding glassware was oven dried (120 °C) and cooled under a stream of argon gas.
Aryl Grignard reagents such as phenyl magnesium or 4-methoxyphenyl magnesium were prepared
according to standard procedure. Functionalized aryl Grignard reagents such as 2-cyanophenyl magnesium chloride or 4-(ethoxycarbonyl)phenyl magnesium chloride were prepared via iodine-magnesium exchange using i-PrMgCl-LiCl according to Knochel’s method. All the Grignard reagents were titrated before use.

4.2 Typical procedure for General procedure for the additions of the mixed diaryl titanate (3ac) to PhCHO.

Under Ar atmosphere, a solution of 4-MeOC₆H₄MgBr (2.5 mmol, 1.0 M in THF) was added dropwise to a solution of tbepc (615 mg, 2.5 mmol) in 10 mL THF at 0 °C and stirred for 2 h at that temperature. To this mixture was added dropwise 4-(ethoxycarbonyl)phenyl magnesium chloride (2.5 mmol, 1.0 M in THF). The resulting mixture stirred at 0 °C for 0.5–1 h. PhCHO (2.5 mmol, 265 mg) was added into the mixture at 0 °C and reacted at this temperature for 6 h (monitored by TLC). The reaction was quenched with saturated aqueous NH₄Cl and extracted with ethyl acetate. The organic layer was dried over Na₂SO₄ and concentrated to yield the crude compound, which was purified by column chromatography to yield the desired product 7a (315 mg, yield 58%) and 8c (237 mg, 37%).

5. Typical procedure for iron-catalyzed oxidative couplings of the mixed diaryl titanate (Table 1, entry 9)

Under Ar atmosphere, a solution of PhMgBr (2.5 mmol, 1.0 M in THF) was added dropwise to a solution of tbepc (615 mg, 2.5 mmol) in 10 mL THF at 0 °C and stirred for 2 h at that temperature. To this mixture was added dropwise 2-cyanophenyl magnesium chloride (2.5 mmol, 1.0 M in THF). The resulting mixture stirred at 0 °C for 0.5–1 h. The solution of FeCl₃ (32.5 mg, 0.2 mmol), TMEDA (58 mg, 0.5 mmol) in THF (5 ml) was added in at one portion. The Ar atmosphere was changed into O₂ atmosphere (applied by an oxygen bag). The thus-obtained mixture was stirred at 0 °C until the completion of the reaction (monitored by TLC) (Note). The reaction was quenched with saturated aqueous Na₂CO₃ and diluted with CH₂Cl₂. After being filtered, the mixture was extracted with CH₂Cl₂. The organic layer was dried over Na₂SO₄ and concentrated to yield the crude compound, which was purified by column chromatography to yield the desired product 5lm (350 mg, 78% yield).

Note: The reactions of Aryl Grignard reagents bearing amide groups (Table 1, entries 10-13) were carried out at 10–15 °C.
