1. **Materials and Instruments**

All chemicals and solvents were purchased from commercial suppliers and used without further purification unless otherwise specified. Starting materials 1 and 5 were synthesized according to literature. \(^1\) \(^\text{\textsuperscript{1}}\)H and \(^\text{\textsuperscript{13}}\)C NMR spectra were recorded in deuterated solvents on a Bruker Avance 400 NMR Spectrometer, a Bruker Avance III 500 WB NMR Spectrometer and an Avance 600 NMR Spectrometer. \(^\text{\textsuperscript{1}}\)H NMR chemical shifts are reported in ppm downfield from tetramethylsilane (TMS) reference using the residual protonated solvent as an internal standard. Mass spectra (MALDI-TOF-MS) were determined on a Bruker BIFLEX III Mass Spectrometer.

2. **Optical and Electrochemical Characterization**

The absorption spectra of dyes and sensitized films were measured by a Hitachi Model U-3010 UV-Vis spectrophotometer. Cyclic voltammograms (CVs) were recorded on a Zahner IM6e electrochemical workstation using glassy carbon discs as the working electrode, Pt wire as the counter electrode, Ag/AgCl electrode as the reference electrode, and ferrocene/ferrocnium (Fc/Fc\(^+\)) as an external potential marker for the calibration of potential. 0.1 M tetrabutyl-ammoniumhexafluorophosphate (Bu\(_4\)NPF\(_6\)) dissolved in CH\(_2\)Cl\(_2\) (HPLC grade) was employed as the supporting electrolyte. CH\(_2\)Cl\(_2\) was dried over calcium hydride and degassed prior to measurement.

**Materials**

The FTO conducting glass (FTO glass, fluorine doped tin oxide over-layer, transmission >90% in the visible, sheet resistance 15 Ω square\(^{-1}\)) was obtained from the Geao Science and Educational Co. Ltd. of China. Titania pastes of DSL 90T were purchased from Dyesol. Lithium iodide was from Fluka and iodine, 99.999%, was from Alfa Aesar. The electrolyte employed was a solution of 0.6 M DMPI, 0.05 M I\(_2\), LiI 0.1 M, 0.5 M TBP in acetonitrile and 3-methoxypropionitrile (v:v = 7 : 3).

**Preparation of photovoltaic devices**

A screen-printed layer of TiO\(_2\) particles was used as the photo-electrode. A 15 mm thick film of DSL 90T was printed on the FTO conducting glass. The electrodes coated with TiO\(_2\) pastes were gradually heated under an air flow at 325°C for 5 min, 375°C for 5 min, 450°C for 15 min and 500°C for 15 min. Before immersion in the dye solution, these films were immersed into a 40 mM aqueous TiCl\(_4\) solution at 70°C for 30 min and washed with water and ethanol. Then the films were heated again at 450°C for 30 min followed by cooling to 80°C and dipping into a 3 × 10\(^{-3}\) M solution of dye in acetonitrile for 12 h at room temperature. To prepare the counter electrode, the Pt catalyst was deposited on the cleaned FTO glass by spin coating with a drop of H\(_2\)PtCl\(_6\) solution (0.02 M in 2-propanol solution) with heat treatment at 400°C for 15 min. A hole (0.8 mm diameter) was drilled on the counter electrode by a drill-press. The perforated sheet was cleaned by ultrasound in an ethanol bath for 10 min. As for the assembly of DSSCs, the dye-covered TiO\(_2\) electrode and Pt-counter electrode were assembled into a sandwich type cell and sealed with a hot-melt gasket of 25 mm thickness made of the ionomer Surlyn 1702 (DuPont). The size of the TiO\(_2\) electrodes used was 0.12 cm\(^2\) (i.e., 0.3 mm × 0.4 mm). A drop of the electrolyte was put on the hole in the back of the counter electrode, which was introduced into the cell via vacuum
backfilling. The hole in the counter electrode was sealed by a film of Surlyn 1702 and a cover glass (0.1 mm thickness) using a hot iron bar.

**Photovoltaic performance measurements**

The current–density voltage (J–V) characteristics of the DSCs were measured by recording J–V curves using a Keithley 2400 source meter under the illumination of AM 1.5 G simulated solar light (Newport-91160 equipped with a 300 W Xe lamp and an AM 1.5 G filter). The incident light intensity was calibrated to 100 mW cm$^{-2}$ with a standard silicon solar cell (Newport 91150V). Action spectra of the incident monochromatic photon-to-electron conversion efficiency (IPCE) for the solar cells were obtained with a Newport-74125 system (Newport Instruments). The intensity of monochromatic light was measured with a Si detector (Newport-71640). The electrochemical impedance spectroscopy (EIS) measurements of all the DSCs were performed using a Zahner IM6e Impedance Analyzer (ZAHNER-Elektrik GmbH & CoKG, Kronach, Germany). The frequency range is 0.10 Hz–100 kHz. The applied voltage bias is −0.70 V with a magnitude of the alternative signal of 10 mV.
