1. Materials and Methods

As in ref. S1, Supporting Information. Briefly, reagents for synthesis were mostly purchased from Fluka, Sigma-Aldrich, and Across. Fullerene C_{60} was purchased from IoLiTec Ionic Liquids Technologies GmbH (Heilbronn, Germany). Indium tin-oxide (ITO) coated glass substrates were obtained from Präzisions Glas & Optik GmbH (Iserlohn, Germany). Reactions were performed under N\textsubscript{2} or Ar atmosphere when specified.

Unless stated otherwise, column chromatography was carried out on silica gel 60 (Fluka, 40-63 \mu m). Analytical (TLC) and preparative thin layer chromatography (PTLC) was performed on silica gel 60 (Fluka, 0.2 mm) and silica gel GF (Analtech, 1 mm), respectively. UV-Vis spectra were recorded on a JASCO V-650 spectrophotometer equipped with a stirrer and a temperature controller (25 ± 0.1 °C) and are reported as maximal absorption wavelength \( \lambda \) in nm (extinction coefficient \( \varepsilon \) in \( \text{M}^{-1}\text{cm}^{-1} \)). Melting points (m.p.) were recorded on a heating table from Reichert (Austria) and uncorrected. IR spectra were recorded on a Perkin Elmer Spectrum One FT-IR spectrometer (ATR, Golden Gate) and are reported as wavenumbers \( \nu \) in cm\textsuperscript{-1} with band intensities indicated as s (strong), m (medium), w (weak), br (broad). \textsuperscript{1}H and \textsuperscript{13}C NMR spectra were recorded (as indicated) either on a Bruker 300 MHz, 400 MHz, 500 MHz or 700 MHz spectrometer and are reported as chemical shifts (\( \delta \)) in ppm relative to TMS (\( \delta = 0 \)). Spin multiplicities are reported as a singlet (s), doublet (d), triplet (t), quartet (q) and quintet (quint) with coupling constants (\( J \)) given in Hz, or multiplet (m). \textsuperscript{1}H and \textsuperscript{13}C resonances were assigned with the aid of additional information from 1D & 2D NMR spectra (H, H-COSY, DEPT 135, HSQC and HMBC). ESI-MS for the characterization of new compounds was performed on an ESI API 150EX and is reported as mass-per-charge ratio m/z (intensity in %, [assignment]). ESI-HRMS for the characterization of new compounds were performed on a QSTAR Pulsar (AB/MDS Sciex) and are reported as mass-per-charge ratio m/z calculated and observed, MALDI-TOF on Bruker Autoflex. Electrochemical measurements were done on an Electrochemical Analyzer with Picoamp booster and Faraday cage (CH Instruments...
Photocurrents were measured using a 150 W solar simulator (Newport) and an Electrochemical Analyzer (CH Instruments 660C). The irradiation power was measured using a radiant power energy meter (Newport model 70260).

2.2. Electrochemistry

The reduction potentials of the fullerenes 5-9 were determined using differential pulse voltammograms (DPV, scan rate 100 mV/s) vs Fe⁺/Fc in DCM (supporting electrolyte: 100 mM Bu₄NPF₆, working electrode: glassy carbon electrode, counter electrode: Pt wire, reference electrode: Ag wire in a 10 mM AgNO₃/0.1 M Bu₄NPF₆ in acetonitrile solution, Supporting Figure S1). LUMO energies vs vacuum were calculated from reduction peak in DPV using the Supporting equation (S1). The optical band gap $E_{g}^{\text{opt}}$ was calculated from the onset of the lowest energy band using the Supporting equation (S2). HOMO energy levels were estimated from difference between $E_{\text{LUMO}}$ and $E_{g}^{\text{opt}}$ (S3).

$$E_{\text{LUMO}} = -5.1 \text{ eV} - E_{\text{DPV}} \text{ vs (Fc}^+/\text{Fc})$$  \hspace{1cm} (S1)
\[ E_{g}^{\text{opt}} = \frac{1240}{\lambda_{\text{max}}^{\text{onset}}} \text{(nm)} \]  

(S2)

\[ E_{\text{HOMO}} = E_{\text{LUMO}} - E_{g}^{\text{opt}} \]  

(S3)

2.3. Stack Exchange

The SOSIP electrode based on photosystem ITO-NDI-Benzaldehyde (ITO-NDI-B) was prepared according to the reported procedures.\textsuperscript{56} The obtained electrode was treated with aqueous NH\textsubscript{2}OH (1 M) for 24 h at 40 °C, leading to the photosystem ITO-NDI. This prepared electrode was dipped in a solution of corresponding dyads in DMSO and acetic acid (9:1, 10 mM) and shaken for 24 h at 40 °C. The desired ITO-NDI-T4-Fullerene (ITO-NDI-F) photosystem was obtained when no more changes in UV-vis absorption spectra were observed (Supporting Scheme S3 and Figures S2-3). The yield of stack exchange was roughly estimated from the molar ratio \( R \) obtained from the absorbances of the film after stack exchange at 390 nm and 450 nm by using following equations:

\[
A'_{\text{at 390 nm}} = \varepsilon'_{\text{NDI}}[\text{NDI}] + \varepsilon'_{\text{dyad}}[\text{dyad}]
\]

\[
A''_{\text{at 450 nm}} = \varepsilon''_{\text{NDI}}[\text{NDI}] + \varepsilon''_{\text{dyad}}[\text{dyad}]
\]

where \( A' \) and \( A'' \) are the absorbances at 390 nm and 450 nm, \( \varepsilon'_{\text{NDI}} \) and \( \varepsilon''_{\text{NDI}} \) are the molar absorption coefficients of NDI at 390 nm and 450 nm, and \( \varepsilon'_{\text{dyad}} \) and \( \varepsilon''_{\text{dyad}} \) are the molar absorption coefficients of the corresponding dyad at 390 nm and 450 nm, respectively. Quantitative yield was assumed for a 2:1 ratio (\( R = 2.0 \)).

2.4. Photosystem Characterization

Photocurrent measurements. The final triad photosystems were used as a working electrode with a Pt wire as a counter electrode and Ag/AgCl as a reference electrode. The electrodes were
immersed in a deaerated (by bubbling Ar gas) aqueous solution of TEOA (50 mM) and Na$_2$SO$_4$ (0.1 M) and irradiated with a solar simulator (area of irradiation: $a \sim 0.5 \text{ cm}^2$). Changes in current upon on-off switching of irradiations were measured at 0 V vs Ag/AgCl unless stated. The power of irradiation was 88 mW cm$^{-2}$ unless stated otherwise. Bimolecular recombination efficiencies $\eta_{\text{BR}}$ were calculated from the dependence of photocurrent densities ($J$) to the irradiation power ($I$) using the Supporting equations (S4) and (S5).$^7$

\[ J \propto I^\alpha \quad \text{(S4)} \]

\[ \eta_{\text{BR}} = \alpha^{-1} - 1 \quad \text{(S5)} \]

Activation energies ($E_a$, eV) of the system were calculated from the dependence of photocurrent densities ($J$, A/cm$^2$) to the temperature ($T$, K) using the Supporting equation S6.$^8$

\[ J(T, I_{\text{light}}) = J_{\infty}(I_{\text{light}}) e^{-\frac{E_a}{kT}} \quad \text{(S6)} \]

where $I_{\text{light}}$ is the irradiation power and $k$ is the Boltzmann constant $8.617 \times 10^{-5}$ eV / K. $I_{\text{light}} = 88$ mW cm$^{-2}$ was used for determining $E_a$ values.

2.5. Time Resolved Fluorescence

Fluorescence dynamics on the nanosecond timescale were measured by a time-correlated single photon counting (TCSPC). Excitation was performed at 395 nm using ~60 ps pulse at 10 MHz produced by a laser diode (picoquant, LDH-P-C-400B). The full width at half-maximum (FWHM) of the instrument response function (IRF) was around 200 ps. Faster fluorescence dynamics were monitored by fluorescence up-conversion (FU) using the same setup as reported.$^9$ Excitation was performed at 400 nm with the frequency-doubled output of a Kerr-lens mode-locked Ti:sapphire laser (Spectra-Physics, Mai Tai). The pump intensity on the sample was around 5 $\mu$J cm$^{-2}$, and the
FWHM of the IRF was ca. 200 fs. The sample solutions in acetonitrile were located in a 1 mm rotating cell and at an absorbance of about 0.05 at the excitation wavelength.

The fluorescence decays are mono-exponential. They can be reproduced with a convolution of the IRF and a mono-exponential decay. For the analysis of the femtosecond FU data, the decay time found from TCSPC was fixed. FU measurements were made at three different wavelengths (480, 510 and 540 nm). A global analysis of the three sets of data was then made. A three-exponential decay had to be used. The results from the analysis are summarized in Table S3. (The origin of $\tau_3$ of all dyads is unclear. It could originate from a residual impurity of $T_4$, but such an impurity was not detectable and thus not removable by other spectroscopic and analytical methods. In situ hydrolysis of the bridging oximes is unlikely considering their stability but cannot be fully excluded.)
