Experimental Section

General experimental: Alkynes, AIBN or AMBN, and metal catalysts used in this reaction were obtained from commercial sources and used without further purification. Flash column chromatography was performed using silica gel (300-400 mesh). Analytical thin-layer chromatography was performed using glass plates pre-coated with 200-300 mesh silica gel impregnated with a fluorescent indicator (254 nm). NMR spectra were recorded in CDCl₃ on a Varian Inova-400 NMR spectrometer (400 MHz); chemical shifts were reported in ppm with the solvent signals as reference, and coupling constants (J) were given in Hertz. The peak information was described as: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, comp = composite. Products were characterized by comparison of ¹H NMR, ¹³C NMR and TOF-MS data in the literatures.

I. General procedure for the cyanation of alkynes.

To a Schlenk tube equipped with a magnetic stir bar was added alkynes (0.3 mmol), AMBN (0.6 mmol, 115.4 mg) or AIBN (0.6 mmol, 98.5 mg), Cu(NO)₃·3H₂O (20 mol%, 14.5 mg) and acetonitrile (4.0 ml). The Schlenk tube was then charged with an air balloon and the mixture was stirred at 80 °C for 12 hours. At the end of the reaction, the reaction mixture was cooled to room temperature. After removal of the solvent, the residue was purified by column chromatography on silica gel (eluent: petroleum ether: ethyl acetate = 60:1) to afford the pure products.

II. General procedure for the synthesis of vinyl isobutyronitrile.

To a Schlenk tube equipped with a magnetic stir bar was added alkynes (0.6 mmol), AIBN (0.15 mmol, 24.6 mg) or AMBN (0.15 mmol, 28.8 mg), Cu(OAc)₂·H₂O (20 mol%, 12.0 mg) and pyridine (2.0 ml). The mixture was stirred at 80 °C for 12 hours under argon atmosphere. At the end of the reaction, the reaction mixture was cooled to room temperature. After removal of the solvent, the residue was purified by column chromatography on silica gel (eluent: petroleum ether: ethyl acetate = 30:1) to afford the pure products.

In order to further explore the applicability of the developed protocol, a few more reactions were conducted by using AMBN as cyanating reagent. Firstly, 3-(4-bromophenyl)propionic acid can successfully afford 2g in 45% yield through a decarboxylative cyanation process. However, no desired product was generated when phenylpropionic acid was applied to react with AIBN (eq 2), nor the self-coupling byproduct. These results suggest that these two processes follow different reaction pathways.

A few reactions were conducted to investigate the mechanism. Both of the reactions under air or argon were significantly inhibited when TEMPO (2.0 equiv) was added (eq 3 and eq 4 respectively), which strongly suggests that these reactions proceeded through radical process. As expected, product 2a was successfully obtained when (phenylethynyl)copper reacted with AMBN under standard condition (eq 5), indicating that (phenylethynyl)copper could be a very possible intermediate in this reaction. While no vinyl isobutyronitrile product was detected in the reaction of (phenylethynyl)copper with AIBN (eq 6). This reaction can't proceed even stoichiometric amount of water or ethanol were added as protonation reagents, which suggests that another reaction pathway should be involved besides the (phenylethynyl)copper intermediate.
