Supplementary Information

Coordination-directed self-assembly of a simple benzothiadiazole-fused tetrathiafulvalene to low-bandgap metallogels

Anneliese M. Amacher, Josep Puigmarti-Luis, Yan Geng, Victor Lebedev, Vladimir Laukhin, Karl Krämer, Jürg Hauser, David B. Amabilino, Silvio Decurtins and Shi-Xia Liu

Experimental

Materials and methods All reagents were purchased from commercial sources and used without further purification. 4,5-Bis(propylsulfanyl)-1,3-dithiol-2-thione and [1,3]dithiolo[4,5-]<sub>f</sub>-2,1,3-benzothiadiazole-6-one were synthesized as previously published.<sup>1</sup> <sup>1</sup>H and <sup>13</sup>C NMR spectra were recorded on a Bruker Avance 300 spectrometer operating at 300 MHz and 75.5 MHz, respectively. Chemical shifts are reported in parts per million (ppm) and are referenced to the residual solvent peak (chloroform, <sup>1</sup>H = 7.26 ppm, <sup>13</sup>C = 77.0 ppm). Coupling constants (J) are given in hertz (Hz). Peak multiplicities are described in the following way: s, singlet; t, triplet; m, multiplet. HRMS data was obtained with ESI (electrospray ionization) mode. FTIR spectra were recorded on a Perkin Elmer One FTIR spectrometer. Differential scanning calorimetry was performed in a MettlerToledo DSC823e under N<sub>2</sub> at a heating rate of 5 °C/min. Powder X-ray diffraction in reflection geometry was carried out. The patterns as a function of temperature were measured with Cu Kα radiation (λ = 1.54 Å) in a 0.3 mm capillary in Debye-Scherrer geometry on a STOE StadiP powder diffractometer. The patterns are shown with 20 mm offset on the intensity scale. Energy dispersive X-ray spectroscopy (EDX) analysis of xerogels was obtained on a Noran SIX NSS200 dispersive X-ray spectrometer. Scanning electron microscopy (SEM) measurements were carried out on Hitachi S-3000 N. Magnetic susceptibility measurements were made on a Quantum Design MPMS SQUID-XL magnetometer under an applied magnetic field of 10<sup>3</sup> Oe between 300 and 2 K. EPR spectra were obtained with an X-Band Bruker ELEXYS 500 spectrometer equipped with a rectangular cavity operating in a T102 mode, a Bruker variable temperature unit, a field frequency lock system, and an NMR gaussmeter. The modulation amplitude was kept well below the line width, and the microwave power was well below saturation.

Synthesis of 6-[4,5-bis(propylthio)-1,3-dithiol-2-ylidene][1,3]dithiolo[4,5-]<sub>f</sub>-2,1,3-benzothiadiazole (I) To a 10-20 ml microwave vial (Biotage) was added [1,3]dithiolo[4,5-]<sub>f</sub>-2,1,3-benzothiadiazole-6-one (0.64 g, 2.8 mmol), 4,5-bis(propylsulfanyl)-1,3-dithiol-2-thione (1.60 g, 5.66 mmol), toluene (4 mL), and triethylphosphite (5 mL). Ar was bubbled through the mixture for 10 minutes. The mixture was then submersed in an oil bath at 130 °C for 30 minutes. After cooling down to room temperature, the reaction mixture was poured into methanol (75 mL). The crude precipitate was recovered by filtration and rinsed copiously with methanol. Pure compound I was obtained after column chromatography on silica gel with gradient elution of dichloromethane and hexane in 61% yield. <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>, δ): 7.78 (s, 2H), 2.82 (t, J = 7.23 Hz, 4H), 1.68 (m, J = 7.28 Hz, 4H) 1.03 (t, J = 7.33 Hz, 6H); <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub>, δ): 153.52, 142.73, 127.84, 116.06, 111.80, 38.35, 23.16, 13.15; HRMS (ESI) m/z calculated for C<sub>16</sub>H<sub>16</sub>N<sub>2</sub>S<sub>7</sub>, 459.9353; found, 459.9343.

General Procedure for Preparation of Metallogels For a typical gel formation reaction, 0.04 mmol of I was dissolved in 1 mL of solvent in a vial. Then, 0.1 mL of an ethanol solution of metal(II) salt at concentration of 0.4 M was added. The vial was closed with a screw cap and left at room temperature. The gelation was found to occur in less than 5 minutes. To make films of the gel, 11.5 mg of ligand I was dissolved in 0.5 mL of o-dichlorobenzene to which was added a solution of 4.26 mg of copper chloride in 0.05 mL of ethanol. A loose gel formed. It was put in between two glass...
slides and compressed firmly and the slides were rubbed together. The gel particles broke down and blended together. Then the glass slides were slid apart in one motion and left to dry.

**Preparation of Samples for Electrical Resistivity Measurements** A sample of the xerogel was deposited onto a flat SiO₂ wafer by drop-casting (total area was around 0.7 cm²) and was exposed to iodine vapors for 2 minutes. Temperature resistance dependence was measured using a standard four-probe dc method. Four annealed platinum wires (20 µm in diameter) were attached to the surface of the xerogel (which had an average thickness of 0.4 µm according to atomic force microscopy) using conductive graphite paste. The current used for measurements was 1 µA.

**AFM Experiments** CS AFM studies were performed on a 5500LS SPM system from Agilent Technologies using the Resiscope module. A contact mode with a bias voltage applied to the sample while scanning with a grounded conducting Pt-Ir coated silicon tip (force constant around 1.2 N/m) were used. Contact to the sample was made through the graphite substrate.

**Crystal Structure Determination** A crystal of 1 was mounted with Paratone-N on a glass needle and used for X-ray structure determination at -100 °C. All measurements were made on a Oxford Diffraction SuperNova area-detector diffractometer using mirror optics monochromated Mo Kα radiation (λ = 0.71073 Å). The unit cell constants and an orientation matrix for data collection were obtained from a least-squares refinement of the setting angles of 7789 reflections in the range 1.74° < θ < 28.12°. A total of 1743 frames were collected using ω scans, 80 seconds exposure time and a rotation angle of 0.5° per frame, and a crystal-detector distance of 65.0 mm.

Data reduction was performed using the CrysAlisPro² program. The intensities were corrected for Lorentz and polarization effects, and an absorption correction based on the multi-scan method using SCALE3 ABSPACK in CrysAlisPro² was applied.

The structure was solved by direct methods using SIR92,³ which revealed the positions of all non-hydrogen atoms of the title compound. The non-hydrogen atoms were refined anisotropically. The H-atoms were placed in geometrically calculated positions and refined using a riding model where each H-atom was assigned a fixed isotropic displacement parameter with a value equal to 1.2 Ueq of its parent atom (1.5 Ueq for the methyl groups). Refinement of the structure was carried out on F² using full-matrix least-squares procedures, which minimized the function Σw(Fo² – Fe²)². The weighting scheme was based on counting statistics and included a factor to downweight the intense reflections. All calculations were performed using the SHELXL-97⁴ program.

Crystallographic data of 1, CCDC 1005516, can be obtained free of charge from the Cambridge Crystallographic Data Centre via [www.ccdc.cam.ac.uk/data_request/cif](http://www.ccdc.cam.ac.uk/data_request/cif).
Table S1. Gelation test in different transition metal chlorides (0.04 mmol of I in 1 mL of CHCl₃, 0.04 mmol of metal salt in 0.1 mL of ethanol, except for 0.15 mL of ethanol for CdCl₂).

Figure S14. Low angle part of the diffraction patterns of undoped (a) and doped (b) Cu xerogel of 1 as a function of temperature (green curve at 175 °C, red curve at 150 °C, blue curve at 100 °C).
Figure S15. In (a) SEM image of a freshly doped copper chloride-based xerogel of 1 and in (b) SEM image of the same sample after the annealing cycle was applied.

Figure S16. An ORTEP (50% probability ellipsoids) structure (top) and packing diagram (down) of 1.
The crystal of **1** is twinned by inversion with a ratio of 0.63:0.37. There are two molecules per asymmetric unit (Figure S16). One \( n \)-propyl moiety of each molecule is disordered over two sites with occupancies 0.599:0.401 and 0.607:0.393. There are two molecules per asymmetric unit. In the crystal lattice, the molecules are stacked in a head-to-tail manner along \( b \)-axis through \( \text{N} \cdots \text{S} \) contacts of 3.282 Å. There are no \( \text{S} \cdots \text{S} \) close contacts, however, some \( \text{C} \cdots \text{S} \) close contacts of 3.472 Å and unconventional intermolecular hydrogen bonds \( \text{C-H} \cdots \text{N} \) in a range of 3.298 to 3.444 Å are observed.
