General Considerations: All reactions were carried out under an argon atmosphere in flame-dried glassware. Syringes which were used to transfer anhydrous solvents or reagents were purged with argon prior to use. THF was continuously refluxed and freshly distilled from sodium benzophenone ketyl under nitrogen. Methyl tert-butyl ether (MTBE) was freshly distilled from sodium benzophenone ketyl under nitrogen. Yields refer to isolated yields of compounds estimated to be >95% pure as determined by $^1$H-NMR (25°C) and GC-analysis. Chemical shifts are reported as $\delta$-values in ppm relative to the solvent peak. NMR spectra were recorded on solutions in CDCl$_3$ (residual chloroform: $\delta$ = 7.25 ppm for $^1$H-NMR and $\delta$ = 77.0 ppm for $^{13}$C-NMR). For the characterization of the observed signal multiplicities the following abbreviations were used: s (singulet), d (doublet), t (triplet), dd (doublet of doublet), ddd (doublet of doublet of doublet), dt (doublet of triplet), dq (doublet of quartet), q (quartet), qn (quintet), m (multiplet) as well as br (broad). All reagents obtained from commercial sources were used without any further purification unless otherwise stated.
Typical Procedure for the Preparation of Benzylzinc(II) Chlorides (1a-i) (TP 1)

A dry and argon-flushed Schlenk-tube, equipped with a magnetic stirring bar and a rubber septum, was charged with LiCl (0.53 g, 12.5 mmol, 1.25 equiv) and heated up to 450 °C for 5 min under high vacuum. After cooling to room temperature under vigorous stirring, ZnCl₂ (1.51 g, 11.0 mmol, 1.10 equiv) was added under argon, the Schlenk-tube was heated to 320 °C for 5 min, cooled to room temperature and charged with magnesium turnings (0.58 g, 24.0 mmol, 2.40 equiv). Freshly distilled THF (10-15 mL) was added and the reaction mixture was stirred at room temperature for a given time until full conversion of the starting material was observed. The completion of the metatation was monitored by GC-analysis of hydrolysed and iodolysed aliquots. When the oxidative insertion was complete, the solution of the corresponding benzylzinc(II) chloride was separated from the resulting salts via a syringe equipped with a filter and transferred to another pre-dried and argon-flushed Schlenk-tube, before being titrated against iodine.

Typical Procedure for the Cobalt-Catalyzed Cross-Coupling of Benzylzinc(II) Chlorides (1a-i) with Electrophiles (TP 2)

A dry and argon-flushed Schlenk-flask, equipped with a magnetic stirring bar and a rubber septum, was charged with CoCl₂ (5 mol%, ≥ 97% pure) and heated up to 450 °C for 5 min under high vacuum. After cooling to room temperature, the corresponding electrophile (1.0 equiv), freshly distilled MTBE (methyl tert-butyl ether) and isoquinoline (10 mol%) were added. Thereupon, the benzylzinc(II) chloride solution (1.30-1.50 equiv) was dropwise added at room temperature and the reaction mixture was stirred for a given time at 50 °C. The reaction mixture was monitored by GC-analysis of quenched aliquots. A saturated aqueous solution of NH₄Cl was added and the aqueous layer was extracted three times with EtOAc (3 × 75 mL). The combined organic layers were dried over MgSO₄, filtered and concentrated under reduce pressure. Purification of the crude products by flash column chromatography afforded the desired products.
