1. Influence of Cu₂O seed layer thickness on the preferred orientation of NiO

The growth conditions of 1 Pa total pressure and 11 sccm O₂ flow rate, have been used to grow Cu₂O seed layers with 60, 120 and 400 nm thickness. 200 nm NiO layers with the growth conditions of 0.5 Pa total pressure and 11 sccm O₂ have been deposited on the top of these Cu₂O seed layers. As shown in Fig. S1, all Cu₂O seed layers can promote the <111> oriented NiO. Thicker seed layer is required to get a better crystallization of the NiO layer.

Fig. S1: (a) X-ray diffractograms of 200 nm NiO deposited on Cu₂O seed layers with different thickness. (b) Magnified (111) diffraction peaks.

2. Influence of air-exposed Cu$_2$O seed layer surface on the preferred orientation of NiO

The influence of air-contaminated Cu$_2$O seed layer on the growth orientation of NiO has been investigated. A <111> oriented Cu$_2$O layer with 360 nm was grown first, then the sputtering chamber was opened and the Cu$_2$O surface was exposed to air atmosphere for one hour. Later, the sputtering chamber was closed leaving plenty of time for surface hydroxydation and pumped to 10$^{-4}$ Pa again. Subsequently, the NiO layer (200 nm) was grown on the air-exposed Cu$_2$O seed layer without any plasma cleaning. X-ray diffractogram shows that the NiO in this bilayer thin film still has the <111> preferred orientation (see Fig. S2), which indicates that contamination of Cu$_2$O seed layer in air is not able to prevent the growth of <111> oriented NiO.
