Supporting information
1. Experimental Details

All chemicals were purchased from Sigma Aldrich as used as received. The electrode used were made from 99.9% pure copper. The electrodes were inserted between 2 PTFE plates, which only allowed a small square opening (6.26 mm × 6.26 mm) to be in contact with the synthesis solution. The potentiostat used was an AUTOLAB PGSTAT302N.

Scanning Electron Microscopy (SEM) images were obtained with a JEOL JSM 6010LA setup. N₂ and CO₂ sorption analysis were carried out in a Micromeritics instrument Tristar II. The samples were pre-treated before measurement by outgassing under vacuum at a temperature of 393 K for 16 hrs.

The powder X-ray diffraction measurements were performed on a Bruker D8-Advance diffractometer operated in Bragg-Brentano geometry, equipped with a Co-Kα source (λ = 1.78897 Å). The diffraction data for MOFs found in bulk were collected over an angle range from 5° to 62° and for MOFs samples obtained on the electrode surface from 2° to 80° with a step width of 0.02° and scan speed of 0.2°/s.

2. Electrochemical synthesis of Copper MOFs

a. Synthesis of MOFs as bulk powder
200 mg of linker (H₃BTC or H₃TATB) and 25 mg of electrolyte (MTBS) were dissolved in 8 mL of 96% ethanol. The solution was mixed in a home-built, Teflon electrochemical cell (~10 mL, see literature for details of larger version of this cell¹) at either room temperature or 70°C for high-temperature synthesis with two copper electrodes spaced 2.4 mm apart. Constant current of 1 mA was applied for 10 h to obtain the material in solution. The material was then filtered and washed with ethanol overnight at 75°C. The material was then filtered again and dried at 100°C for 2 h.

b. Synthesis of MOFs as surface supported film
100 mg of linker (H₃BTC or H₃TATB) and 25 mg of electrolyte (MTBS) were dissolved in 8 mL of 96% ethanol. The solution was mixed in the electrochemical cell at room temperature with two electrodes, copper mesh as anode and copper electrode as cathode, which were spaced 2.4 mm apart. Cyclic pulses of 2 mA/5 s and 0 mA /5 s (or 1 mA/5s and 0 mA/5s) were applied for 12 cycles (60 s of current). The meshes were washed with ethanol at room temperature overnight and dried at 100°C for 2 h

c. Optimization procedure for surface growth
3.15 g of H₃BTC and different concentrations of MTBS (155-623 mg, i.e. 0.5-2 mmol) were dissolved in 100 mL of 96% ethanol. The solution was mixed in the electrochemical cell at room temperature with two copper electrodes spaced 3 cm apart with a circular opening of 25 mm in contact with solution (area 4.9 cm²). Cyclic pulses of 50 mA/5 s and 0 mA/5 s were applied to keep the current density constant with other experiments. Different pulse cycles were applied to obtain the crack-free uniform layer. The meshes were washed with ethanol overnight and dried at 100°C for 2 h.
Figure S1. Molecular structures of the two linkers used in the study: H$_3$BTC (a) and H$_3$TATB (b).
3. Powder X-ray diffraction, refinement and structural details for MOFs obtained in bulk and surface-supported.

Figure S2. Comparison of XRD patterns of CuBTC obtained in bulk (experimental) and HKUST-1 (simulated).

Rietveld refinement of CuTATB obtained in bulk has been performed with EXPO2014 \(^2\), by which zero offset, scale factor, eight background terms and profile parameters as a PearsonVII function were refined.
Figure S3. Rietveld refinement plot for CuTATB MOF obtained in bulk. The experimental data are presented as black solid line, the calculated data by red circles and difference as blue solid line. The Bragg positions of the peaks are represented as green sticks.

Table S1. Unit cell parameters for CuTATB (obtained in bulk) determined by Rietveld refinement of experimental XRD pattern and compared with CuBTB [3]

$^iR_p = \Sigma |y_{i,o} - y_{i,c}| / \Sigma |y_{i,c}|; \quad ^{ii}R_{wp} = \left[ \Sigma w_i(y_{i,o} - y_{i,c})^2 / \Sigma w_i(y_{i,c})^2 \right]^{1/2}$
Figure S4. Simplification of CuTATB structural units: (a) TATB tripod linker represented as a 3-connected node; (b) paddlewheel copper unit represented as a 4-connected node. (c) Topological view of CuTATB highly interpenetrated net where 3-c nodes of TATB are drawn as violet centres and 4-c nodes of dimeric copper unit as orange centres. (d) The four-component interpenetration in CuTATB polymeric network where each independent polymeric frame is binodal 3,4-connected of sur topological type (each independent net is drawn with different colour).
Topological analyses of CuTATB structures have been performed using ToposPro software package [4]. All the interpenetration nets have the topology of sur-type net and the interpenetration type belongs to a rare class IIIa [5]. As shown in Fig. S5, the interpenetration of four equivalent sur-nets realized by four kinds of interwoven rings (Hopf links): six- and eight-membered rings (b); eight- and eight-membered rings (c); ten- and eight-membered rings (d); ten- and ten-membered rings (e).
Figure S6. Comparison of the pattern of CuTATB scratched from the electrode surface (green) and simulated patterns of PCN-6 structure (red) and HKUST-1 (blue). The dashed lines indicate the most intense peak of the measured spectrum.
Topological analysis of CuTATB structure grown on the electrode surface has been performed using ToposPro software package [4]. All the interpenetration nets have the topology of tbo-type net and the interpenetration type belongs to a class IIa [5]. As shown in Fig. S7, the interpenetration of two equivalent tbo-nets realized by three kinds of interweaved rings (Hopf links): eight- and eight-membered rings (b); eight- and ten-membered rings (c); ten- and ten-membered rings (d).
