Gene constructions and cloning for an elastin-like polypeptide (ELP). A 20-repeat polypeptide of Val-Pro-Gly-Xaa-Gly was synthesized in PUC57 plasmid by the genewiz company (Suzhou, China). (VPGXG)\textsubscript{20} was used as the monomer for synthesis of (VPGXG)\textsubscript{60} and Xaa was chosen to be Val:Ala:Gly in a 5:3:2 ratio.\textsuperscript{1} The gene sequence of the monomer (VPGXG)\textsubscript{20} is listed in Table S1 (see supporting information).

PUC57-(VPGXG)\textsubscript{20} was linearized with \textit{PflMI} (2 \textmu L \textit{PflMI}; 3 \textmu L 10×K buffer; 25 \textmu L PUC57-(VPGXG)\textsubscript{20} at at 37 \degree\textsuperscript{C} for 3 h), enzymatically dephosphorylated with alkaline phosphatase, and then purified using a DNA extraction kit (Omega Bio-tek). Another aliquot of the plasmid was codigested with \textit{PflMI} and \textit{BglI} restriction endonucleases to generate the free (VPGXG)\textsubscript{20} insert (2 \textmu L \textit{PflMI} I; 2 \textmu L \textit{BglI} I; 5 \textmu L 10×K buffer; 41 \textmu L PUC57-(VPGXG)\textsubscript{20}). After digestion, the reaction products were separated by agarose gel electrophoresis, and the insert was purified using a DNA extraction kit (Omega Bio-tek).

The monomers were then ligated to the linearized vector (0.4 \textmu L T4 DNA ligase, 2
μL 10×ligation buffer; 2 μL PUC57-(VPGXG)20, 15.6 μL insert, incubated at 22 °C for 20 min). A 10 μL portion of the ligation mixture was combined with 100 μL of chemically competent Escherichia coli cells (DH5α), and the cells were transformed by heat shock (30 min on ice, 90 s 42 °C, 3 min on ice). After addition of 900 μL LB medium, the cells were cultured for 45 min, spread on LB medium agar plates supplemented with ampicillin (50 μg/mL), and incubated at 37 °C. The transformants were verified by their digestions with diagnostic restriction endonucleases and confirmed by DNA sequencing (BGI Tech). The result of this process was a (VPGXG)40 insert in the pUC-57 vector. Subsequent additional round of recursive directional ligation proceed identically for (VPGXG)60. The plasmid pET28a was codigested BamH I and Hind III restriction endonucleases. The pUC-57 vector harboring the (VPGXG)60 gene was codigested BamH I and Hind III restriction endonucleases, and the resulting fragment was ligated into the plasmid pET28a to construct the expression vector pET28a/(VPGXG)60 in Escherichia coli. Fig. S1a shows the SDS-PAGE analysis for the ELP (VPGXG)60 (see supporting information). The ELP was approximately 29.5 kDa in size, in agreement with the theoretically predicted molecular weight the molecular weight. The purified ELP can be reversed from a cloudy suspension to a clear solution at a low temperature (4 °C) (Fig. S1b).

Expression vector construction. The DAAO gene was amplified by PCR using Pfu DNA polymerase with genomic DNA of Trigonopsis variabilis as template using the paired primers (Table S2). The DAAO gene was purified using a DNA extraction kit (Omega Bio-tek) and was then codigested Nco I and BamH I restriction endonucleases. The resulting fragment was ligated into the plasmid pET28a/(VPGXG)60, which has been codigested with Nco I and BamH I restriction endonucleases. Thus the expression vector pET28a/(VPGXG)60-DAAO in Escherichia coli. was constructed.

Lane M: molecular mass marker (KDa); lane 1 is for the supernatants from the third round of inverse transition cycling; lane 2 is for total proteins.
Fig. S4. Deamination of D-alanine catalyzed by free ELP-DAAO (a) and immobilized ELP-DAAO (b).

Reaction conditions: equivalent amount of enzyme was used, 0.1 mg/ml ELP-DAAO; D-alanine (1.30 mM) was dissolved in 1 ml PBS buffer (pH 8.0, 50 mM). The reactions were carried out at 30 °C for 3 min. 200 μl trichloroacetic acid solution (20 % w/v) was then added to the tubes to terminate the reactions. The solutions were centrifuged. 100 μl 2,4-dinitrophenylhydrazine (DNPH) solution (10 mM) was added to the supernatants, incubated at 37 °C for 10 min, and then 700 μl NaOH (1.5 M) was added.
