Materials

All materials were purchased from Sigma-Aldrich and used as received without further purification.

Synthesis

Synthesis of HKUST-1 In a typical synthesis, 1.3576 g Cu(NO\textsubscript{3})\textsubscript{2}·3H\textsubscript{2}O and 0.8400 g benzene-1,3,5-tricarboxylic acid were dissolved in a mixture of N,N-dimethylformamide (15 ml), ethanol (15 ml) and deionized water (15 ml). After being stirred for 5 h, the precipitates were isolated by filtration, washed with mixed solvent of deionized water and ethanol for 3 times.

CuO microspheres The microspheres are obtained from pyrolysis of the as-prepared HKUST-1. The pyrolysis temperatures are based on the TGA results and set at 300 °C. In a typical process, 200 mg HKUST-1 was placed in a tube furnace. Before being heated, the furnace tube was flushed by the mixed gas of 2 vol. % O\textsubscript{2} balanced with helium at a speed of 35 mL/min to remove air. Then the furnace was heated to 300 °C at a rate of 10 °C min\textsuperscript{-1} and kept for different times. Finally, the product was taken out. The reactions conducted in pure N\textsubscript{2} and air are in the same process.

Characterization

The phase of the as-obtained samples was characterized by X-ray powder diffractometer (Bruker D8 Advance) with Cu Ka radiation (\(\lambda=1.5406\) Å). Morphological features were studied using field emission scanning electron microscope (FESEM, JEOL JSM-7600F). Internal structures of the samples were observed by transmission electron microscope (TEM, JEOL JEM-2010). Thermogravimetric analyses (TGA) were firstly performed on a Q500 TGA (TA Instruments) under nitrogen gas flow at 10 °C min\textsuperscript{-1} from room temperature to 900 °C. Then it was conducted in pure air at 10 °C·min\textsuperscript{-1} from room temperature to 300 °C and kept at this temperature for 30 min. The IR spectrum was obtained on a Perkin-Elmer FT-IR spectrophotometer in the 400–2000 cm\textsuperscript{-1} region with a KBr pellet. Nitrogen adsorption isotherms of powder samples were measured with a Micromeritics ASAP 2020 adsorption apparatus at 77 K up to 1 bar. Before starting the adsorption measurements, each sample was activated by heating under vacuum at 373 K for 10 hours. The pore textural properties including Brunauer-Emmett-Teller (BET) surface area and pore size were obtained by analyzing nitrogen adsorption and desorption isotherms with Micromeritics ASAP 2020 built-in software.
Catalytic measurements

The catalytic activity of samples prepared for CO oxidation was tested in a fixed-bed flow reactor with 25 mg catalysts and with a gas flow mixed of CO (1.5 ml/min), O₂ (30 ml/min), and He (60 ml/min). The composition of the effluent gas was analyzed using a gas chromatograph (Agilent, 6890N) equipped with a Carbosieve SH column. After the test of catalytic activity, the fixed-bed was cooled down to 200 °C and kept for 24 h to measure the catalytic stability of samples.
