Supporting information to

Direct biosynthetic cyclization of a distorted paracyclophane highlighted by double isotopic labelling of L-tyrosine

Alexandre Ear, Séverine Amand, Florent Blanchard, Alain Blond, Lionel Dubost, Didier Buisson and Bastien Nay

General information

All reactions were carried out in oven-dried reaction vessels under an atmosphere of argon and in anhydrous solvents, unless otherwise stated. Reactions and purifications were monitored by TLC on Merck silica gel 60 F254 aluminium, using UV absorption then vanillin–H$_2$SO$_4$ (1% vanillin in ethanol + 2% H$_2$SO$_4$), or ninhydrin (3% ninhydrin in EtOH) as staining system. The products were purified by flash chromatography on Geduran silica gel Si 60, 40–63 μm. NMR spectra were recorded on Bruker Avance III HD 400 MHz and 600 MHz spectrometers. Chemical shifts (δ) are quoted in ppm with internal calibration from the residual solvent peak (CHCl$_3$: 7.27, 77.0 ppm; DMSO-d$_5$: 2.49, 39.5 ppm; HDO: 4.79 ppm for 1H and 13C NMR, respectively). All coupling constants (J) are quoted in Hertz. The following abbreviations are used to designate multiplicities: s = singlet, d = doublet, t = triplet, m = multiplet, br = broad. High resolution mass spectra (HR-MS) of synthesized compounds were measured on an Applied Biosystem QSTAR Pulsar-i spectrometer, using electrospray ionization (ESI). Infrared spectra were recorded on a Shimatzu 8400S FTIR spectrometer. Specific rotations were recorded on a Perkin Elmer 341 polarimeter at 20°C (589 nm, Na lamp). The enantiomeric excess of compound 16 was measured by gas chromatography (GC control: Varian 3400) on a chiral column (see synthetic procedure). The enantiomeric excess of tyrosine 17 was measured by UHPLC (Shimadzu Nexera coupled to DAD) on a standard reverse phase column after derivatization (see synthetic procedure). Melting points were measured on a Büchi B-545 apparatus. Detection of pyrrocidines in samples from mycelium extracts were done with the high performance liquid chromatography (Shimadzu, UHPLC Nexera) coupled with mass spectrometry (Shimadzu, LCMS2020) using atmospheric pressure chemical ionization (APCI).

Synthetic procedures and compound data

4-($^{18}$O)Hydroxybenzaldehyde (10)

To a solution of 4-formylphenylboronic acid 9 (1.0 g, 6.67 mmol) in DMF (20 mL) was added the catalyst [Ru(bpy)$_3$Cl$_2$]·6H$_2$O (10 mg, 0.13 mmol) and iPr$_2$NEt (2.32 mL, 13.3 mmol) at room temperature. The reaction was irradiated at 420 nm (blue led)$^1$ at room temperature during 24 h and under an atmosphere of 97.1% isotopically enriched $^{18}$O$_2$. The solution was cooled in an ice bath at 0°C before quenching with 10% aqueous HCl (25 mL). The solution was extracted with Et$_2$O (25 mL x 3). The organic phase was washed with brine (50 mL) and dried over Na$_2$SO$_4$. The crude extract was purified by flash chromatography on silica gel (EtOAc/cyclohexane 1/3) to furnish the compound (10) as a colourless solid (340 mg, 41% or 89 % based on recovered starting material). A loss of isotopic enrichment was

---

found at 86% yield (measured by mass spectrometry, Figure S1), probably due to slight air dilution during the experiment.

$^1$H NMR (400 MHz, CDCl$_3$), $\delta$ (ppm): 9.89 (s, 1H, CHO), 7.83 (d, $J$ = 8.6 Hz, 2H, ortho ArH), 6.99 (d, $J$= 8.6 Hz, 2H, meta ArH), 6.61 (brs, 1H, OH).

$^{13}$C NMR (100 MHz, CDCl$_3$), $\delta$ (ppm): 191.0 (CHO), 164.5 (COH), 132.5 (ortho C$_{Ar}$), 129.0 (meta C$_{Ar}$).

IR (thin film on NaCl pellets) $\nu$ (cm$^{-1}$): 3187, 1682, 1601, 1495, 1296, 1200, 1142, 802.

HRMS (ESI+), $m/z$ calcd. for C$_7$H$_7$O$_2$O$_2$+H$^+$: 125.0488; found: 125.0493.

m.p.: 114-115 °C (lit.$^2$ 115-116 °C).

Figure S1: Mass spectra $^{18}$O-labelled $p$-hydroxybenzaldehyde (10) showing the presence of unlabelled compound.

4-[(18O)Methoxy]benzaldehyde (11)

To a solution of KOH (470 mg, 8.40 mmol) in DMSO (5 mL) was added, at room temperature, the benzaldehyde 10 (260 mg, 2.10 mmol) and MeI (259 µL, 4.20 mmol). The reaction is stirred at room temperature for 3 h, and H$_2$O (15 mL) was then added. The reaction mixture was extracted with DCM (15 mL x 2). The organic layer was dried over Na$_2$SO$_4$ and evaporated to give 4-[(18O)methoxy]benzaldehyde or 4-(18O)anisaldehyde (11) as a clean oily product without further purification (270 mg, 93 %).

$^1$H NMR (400 MHz, CDCl$_3$), $\delta$ (ppm): 9.89 (s, 1H, CHO), 7.84 (d, $J$ = 8.8 Hz, 2H, ortho ArH), 7.02 (d, $J$ = 8.7 Hz, 2H, meta ArH), 3.89 (s, 3H, OCH$_3$).

13C NMR (100 MHz, CDCl3), δ (ppm): 190.8 (CHO), 164.6 (Cα,18OMe), 132.0 (ortho Cα), 130.0 (Cα,CHO), 114.3 (meta Cα), 55.6 (18OCH3).
IR (film on NaCl pellets) ν (cm⁻¹): 2913, 2820, 2707, 1685, 1601, 1579, 1500, 1452, 1403, 1260, 1173, 1002, 810.
HRMS (ESI+), m/z calcd. for C8H8O18O [M+H]⁺: 139.0644; found 139.0640

2-([(Tert-butoxycarbonyl)amino]-(1-13C)acetic acid (12)

To a solution of 1-[13C]glycine (1 g, 13.2 mmol) in a 1:1 mixture of dioxane/H2O (32 mL) was added Boc2O (1.45 g, 6.67 mmol) and Et3N (1.77 mL, 13.2 mmol) at room temperature. After the reaction was left for 2 h at room temperature, dioxane was evaporated and H2O/Et2O (50 mL/80 mL) were added for extraction. The aqueous phase was recovered and its pH was adjusted to 2 with a 1 N solution of HCl. Extraction was performed with AcOEt (50 mL x 2) and the organic layer was dried over MgSO4 and concentrated to furnish the protected N-Boc-(1-13C)glycine 12 as a colorless solid (2.16 g, 93 %) which was used for the next step without further purification.

1H NMR (400 MHz, DMSO-d6), δ (ppm): 12.43 (brs, 1H, COOH), 7.03 (t, J = 6.1 Hz, 1H, NH), 3.58 (d, J = 6.1 Hz, 2H, CH2), 1.39 (s, 9H, O(CH3)3).

13C NMR (100 MHz, D2O), δ (ppm): 174.7 (13COOH), 158.3 (NHCO), 81.6 (OC(CH3)3), 42.0 (d, J_{C–C} = 56.3 Hz, CH2), 28.1 (O(CH3)3).

3 IR (thin film on NaCl pellets) ν (cm⁻¹): 3323, 2985, 2913, 1700, 1502, 1360, 1358, 1221, 1178, 1020.
HRMS (ESI+), m/z calcd. for 13CC6H14NO4 [M+H]⁺: 177.0956; found: 177.0958.
m.p.: 85-86 °C (lit.4 85-88°C).

Methyl (Z)-2-acetamido-3-[4-(18O)methoxyphenyl]-(1-13C)acrylate (13)

The reaction mixture of the [18O]-labelled methoxybenzaldehyde 11 (270 mg, 2.00 mmol), CH3COONa (160 mg, 2.00 mmol), the [13C]-labelled N-Boc-Gly 12 (344 mg, 2.00 mmol) and Ac2O (1.18 mL, 12.5 mmol) was stirred at 40°C for 40 min and then heated to 140 °C for 18 h.5 The reaction was cooled down at room temperature and water (25 mL) was added before stirring at the same temperature for 1 h. The solution was filtered, the brown precipitate was washed with water (5 mL x 2) and then diluted in MeOH (20 mL). After addition of Et3N (0.3 mL, 2.00 mmol), the solution was heated at 80°C for 3 h, then solvents were evaporated. Water (50 mL) and AcOEt (3 x 30 mL) were added for extraction. The organic phase was dried over MgSO4, evaporated and the concentrated crude extract was purified by flash chromatography on silica gel (cyclohexane/EtOAc 1:2), to furnish the desired compound 13 as a brown resin (122 mg, 25 % or 48 % based on recovered starting material).

1H NMR (400 MHz, CDCl3), δ (ppm): 7.44 (d, J = 8.4 Hz, 2H, ortho ArH), 7.40 (s, 1H, NH), 7.07 (s, 1H, =CH–), 6.88 (d, J = 8.4 Hz, 2H, meta ArH), 3.81 (s, 6H, ArOCH3, CO2CH3), 2.15 (s, 3H, NHCOCH3).

3 Isotope shifts were observed, to be compared with unlabelled compound: 13C NMR (100 MHz, D2O), δ (ppm): 171.8 (COOH), 155.8 (NHCO), 78.0 (OC(CH3)3), 41.8 (CH2), 28.2 (O(CH3)3).

HRMS (ESI+), \(m/z\) calcd. for \(^{12}\text{CC}_2\text{H}_8\text{NO}_3^{18}\text{O}[\text{M+H}]^+: 253.1306;\) found: 253.1290.

\([\alpha]_D^{20} = +18^\circ\) (c 0.3, MeOH; lit.\(^8\) +17.8\(^\circ\), c 0.5, MeOH).

m.p.: 103 °C (lit.\(^9\) 104°C).

The enantiomeric excess of 15 was measured by comparison with the racemic mixture, by GC on the chiral column CP chirasil-DEX-CB/25 m-0.32 mm- 0.25 μm, with helium as the carrier gas at 16 psi. A 40 min program was used: 0-25 min (isocratic 150 °C), 25-29 min (gradient of 5 °C/min from 150 to 170 °C), 29-40 min (isocratic 175 °C). The racemic product was injected in GC and two retention times were obtained (rt = 31.345 and 31.731 min). Injection of compound 15 gave a single peak at 31.701 min.

**(2S)-2-Acetamido-3-[4-\(^{18}\text{O}\)hydroxyphenyl]-\(1^{13}\text{C}\)propanoic acid**

To the protected doubly labelled L-tyrosine 15 (111 mg, 0.44 mmol) was added a solution of NaI (72 mg, 0.48 mmol) in 48% aqueous HBr (6 mL, used as received from Aldrich) at room temperature. The mixture was heated at 94°C during 2 h. The reaction mixture was then filtered through a pad of resin Amberlite IR120 (H\(^+\)) washed with H\(_2\)O. The solvent was evaporated to give quantitatively the desired \(N\)-acetyl-L-tyrosine as a colourless solid (99 mg).

---

\(^{14}\) L. Gunter, Journal für praktische Chemie, 1958, 7, 141.

Supplementation of culture broths of *Acremonium zeae* NRRL 13540 with labelled L-tyrosine and metabolic analyses

A preculture of *A. zeae* NRRL 13540 was grown on slants of PDA at 25°C during 7 days. A mixture of hyphal fragments and spores at a density of 10^6 propagules/mL in sterile filtrated glycerol (20 % in water) was prepared from the slants of PDA and served as the inoculum. For a 20 mL culture of CLGB (prepared from an autoclaved then filtered mixture of corn leaves 20 g/L and glucose 20 g/L) in a 50 mL Erlenmeyer, 0.2 mL of the inoculum was added. At 48, 72 and 96 h of culture, 20 mg of the doubly labelled L-tyrosine 17 was supplemented each time into the medium under sterile conditions. After 1 week of culture, the medium was centrifuged at 4000 rpm and 4°C during 40 min, before separation of the mycelium and the medium in two Erlenmeyers. The mycelium was suspended in AcOEt (25 mL) and sonicated during 30 min. Brine (30 mL) was added into the mixture for extraction. The procedure from the suspension in AcOEt was repeated once. The organic extracts were draped over MgSO_4_ and the solvent was evaporated to give the crude fungal extract (2 mg) which was analyzed. The supplementation experiment was performed twice, with a 3-month interval.
Detection of pyrrocidines in the mycelium extracts were performed using a coupled UHPLC-MS instrumentation (UHPLC Nexera and MS2020 from Shimadzu) with an atmospheric pressure chemical ionization (APCI source; ESI was ineffective for ionization of pyrrocidines). Separation was performed on a Kinetex column 1.7µ, C18 (100 Å), 100 x 2.1 mm, from Phenomenex. A 12 min program was used with binary A/B solvent system (solvent A: acetonitrile containing 0.1 % of formic acid; solvent B: deionized water containing 0.1 % of formic acid): 0-1 min [isocratic 30/70], 1-6 min [gradient up to 100/0], 6-12 min [isocratic 100/0], with a flow rate of 0.5 mL/min. The optimum MS parameters for detection of pyrrocidines were set with a Q-array voltage of +52 V, and both DL and Q-array DC voltages at 0 V.

To explain the isotope distribution in pyrrocidines A and B, calculation were performed with the open source mass spectrometry tool mMass (http://www.mmass.org/). The spectra for each isotopomer of pyrrocidines A and B were calculated, taking into account their isotope enrichments and relative proportions (pyrrocidine A is at 71% of pyrrocidine B while peaks at m/z 488 and 493 were adjusted with reference to experimental data). They were combined to get the full spectrum of Figure S3, demonstrating the origin of the intensity of the peak at m/z 489. Experimental and calculated peak intensities are provided in Table S1.

a Fixed as experimental (considered unaffected by the isotope pattern of neighbour peaks).
**Isolation of pyrrocidines B (4) and C (5)**

A CLGB culture medium (1 L) was inoculated with *A. zeae* (10 mL of inoculum) as previously described. After 14 days of culture at 25 °C, the medium was centrifuged at 4000 rpm and 4°C during 40 min, before separation of the mycelium and the medium in two Erlenmeyers. The mycelium was suspended in AcOEt (250 mL) and sonicated during 30 min. Brine (200 mL) was added into the mixture for extraction. The procedure from the mycelium suspension in AcOEt was repeated once. The organic extracts were dried over MgSO₄ and the solvent was evaporated to give the fungal extract. The AcOEt extract (1.3 g) was obtained after evaporation of volatiles. It was degreased with cyclohexane (3 x 100 mL), providing 577 mg of the crude extract.

Pyrrocidine B (4) and C (5) were purified by semi-preparative HPLC (Agilent Technologies 1260 Infinity) coupled to Diode Array Detector, using the following gradient on a C18 Eclipse XDB column from Agilent (21.2 x 150 mm, 5 µm). Mobile phases were solvent A: 95% water (0.05% trifluoroacetic acid)–5% acetonitrile; and solvent B: 5% water (0.05% trifluoroacetic acid)–95% acetonitrile. The separation was achieved at a flow rate of 15 mL/min with the following gradient (A/B): 0-2 min [isocratic 30/70], 2-10 min [gradient up to 3/97], 10-14 min [gradient up to 0/100], 14-17 min [isocratic 0/100], 17-18 min [back to 30/70]. From 577 mg of the crude extract diluted in MeOH (2 injections / volume injected: 200 µL), a mixture of compounds 3 and 4 and pure compound 5 were obtained respectively at retention times 10.2 (7.9 mg, ratio 3/4: 60:40), 10.8 (2.2 mg) minutes. Pyrrocidine C (5) was stable upon storage and could be crystallized from acetonitrile (see below). Apart from crystallography which is described therein for the first time, all data of 5 were consistent with those of the literature. The mixture of pyrrocidines 3 and 4 spontaneously evolved as a mixture of 4 and 5 upon storage in the freezer at −30°C (see note 20 in the article). This new mixture could be separated by the same method as before, providing pyrrocidine B (4) (2.3 mg) whose data were consistent with those of the literature and an additional batch of pyrrocidine C (5) (3 mg).

---

Crystallographic data for pyrrocidine C (5)

Figure S4 displays the X-ray crystal structure of pyrrocidine C (5). Single crystals suitable for X-ray diffraction were obtained by recrystallization from CH$_3$CN. The data analysis showed it to be monoclinic crystals with space group C2.

Figure S4: ORTEP-3 plot of pyrrocidine C. Ellipsoids are drawn at the 50% probability level and H atoms are shown as spheres of arbitrary radius.

The absolute configuration was analysed by using Hooft methods,$^{18,19}$ and the results indicated that absolute structure had been correctly assigned. According to these methods, the probability that the structure is inverted is 0.5 x 10^{-8} (Flack parameter is -0.14(16), 3279 Bijvoet pairs, Bijvoet coverage = 0.65. P2(true) = 1.00. P3(true) = 0.987. P3(rac-twin) = 0.003. P3(false) = 0.5 x 10^{-8}. Correlation coefficient = 0.995).

X-ray data were collected with a Rigaku Rapid II diffractometer equipped with a rotating anode mm007 HF generator and Osmisc mirrors (Cu Kα radiation, λ = 1.54187 Å) using ω-scans. The structure was solved by direct methods with SHELXS-97, and refined with SHELXL-2014/6 (Table S2).$^{20}$ The model was refined using full-matrix least-squares, all non-hydrogen atoms, except those from solvent molecules, were refined with anisotropic displacement parameters and H atoms have been added geometrically and treated as riding on their parent atoms. CH$_3$CN solvent molecule was divided into two parts due to large anisotropic displacement parameters for C24 and N1 atoms, using PART, DFIX and EADP commands. Molecular graphics were computed with Ortep 3.
