I. Synthesis

**General.** Compounds 2¹, 3¹, 12³, 13³, 14⁴, 16⁵, 17⁶, 18², 24⁷, 25⁸, C₆₀(A)₁₂⁴ were prepared according to previously reported procedures. All reactions were carried out in standard glassware under an argon atmosphere. Yields refer to chromatographically and spectroscopically homogeneous materials. Reagents and chemicals were purchased from Sigma-Aldrich and Acros at ACS grade and were used without purification. All reactions were performed using purified and dried solvents: tetrahydrofuran (THF) was refluxed over sodium-benzophenone, dichloromethane (CH₂Cl₂), triethylamine (NEt₃), and pyridine were refluxed over calcium hydride (CaH₂). All reactions were monitored by thin-layer chromatography (TLC) carried out on Merck aluminum roll silica gel 60–F254 using UV light and a molybdate-sulfuric acid solution as revelator. Merck silica gel (60, particle size 0.040–0.063 mm) was employed for flash column chromatography using technically solvent distilled prior to use as eluting solvents. IR spectra (cm⁻¹) were recorded on a Perkin–Elmer Spectrum 65 spectrophotometer. UV/Vis spectra (λ_max in nm (ε)) were recorded on a SPECORD 205 spectrophotometer. NMR spectra were recorded on a JEOL ECX 400 with solvent peaks as reference. All compounds were characterized by ¹H and ¹³C NMR as well as by ¹H-¹H and ¹H-¹³C correlation experiment when necessary. The following abbreviations are used to describe the multiplicities: s = singlet, d = doublet, t = triplet, m = multiplet, br = broad, br s = broad singlet. The numbering of the protons and carbons is analogous to the proton numbers resulting from the name of the compound. Aromatic, acetyl and methyl (carbons and protons) are respectively labeled with "Arom", "Ac" and "Me", quaternary carbons are indicated with a "q" subscript. Chemical shifts (δ) are reported in ppm and referenced indirectly to TMS via the solvent (or residual solvent) signals. MALDI-MS mass spectra were recorded in University of Mons (UMH, Mass Spectrometry Research Group - CISMa) using a Waters QToF Premier mass spectrometer.

To a solution of 23 (0.050 g, 0.0743 mmol, 1 eq) in t-BuOH/H₂O 1:1 (1 mL) was added 25 (0.009 g, 0.0892 mmol, 1.2 eq), sodium ascorbate (0.003 g, 0.0148 mmol, 0.2 eq) and copper (II) sulfate (0.0012 g, 0.00743 mmol, 0.1 eq). The solution was stirred three hours at room temperature afterwards the solvents were evaporated under reduced pressure. The residue was purified by flash chromatography (SiO₂, EtOAc to EtOAc/EtOH 1:1) to afford E (0.044 g, 76%) as a white powder.

II. Biochemical techniques.

Isothermal Titration Microcalorimetry (ITC).

LecB and RSL were produced in *Escherichia coli* and purified on affinity columns as previously described. Lyophilized LecB and RSL were dissolved in buffer (20 mM Tris-HCl, 0.1 M NaCl pH 7.5 with 100 µM CaCl$_2$). Titration was performed using ITC200 microcalorimeter (Malvern Instruments, UK) with a 200 µl sample cell operating at 25°C. Titrations were performed with 20 injections of 2 µl every 120 s.

For direct titration of monovalent probes A to D, the glycompounds (50 mM water stock solution) were diluted to 1 mM in the same buffer as lectins, loaded in the injection syringe, and injected in solution of LecB (100 µM) or RSL (50 µM) in the microcalorimeter cell. For inverse titration of divalent compound E, the lectins LecB (200 µM) or RSL (100 µM) were injected in the cell containing the glycompound (10 µM). The glycofullerenes were dissolved in the same buffer with the addition of 5% DMSO (in both fullerene and lectin solutions). They were loaded in the syringe at concentrations varying from 0.5 to 20 µM and injected in the cell containing either LecB (200 to 400 µM) or RSL (30 to 300 µM).

The experimental data were fitted to a theoretical titration curve using the supplied Origin software, with ΔH (enthalpy change), Ka (association constant) and n (number of binding sites per monomer) as adjustable parameters. Free energy change (ΔG) and entropy contributions (TΔS) were derived from the equation ΔG = ΔH − TΔS = -RT ln Ka (with T as the absolute temperature and R = 8.314 J mol$^{-1}$ K$^{-1}$). Two or three independent titrations were performed for each tested ligand.

Model Building

The C60 fullerene starting structure was generated using Nanotube Modeler Software (JCrystalSoft, jcrystal.com). The attached linkers decorated with fucose were built in their extended conformation using the molecular editor from the Sybyl-X suite (Certara, www.certara.com), and structures were optimized for removing any steric conflict with the Tripos force field.[2] Crystal structures of LecB/fucose (PDB code 1GZT)[4] and RSL/α-methylfucoside (PDB code 2BT9)[2] were used for building the complexes. Docking of glycosylated fullerenes in the proteins binding sites was performed by fitting the fucose residues from fucosylated fullerenes to the same sugar in the binding site of crystal structure with the use of the fitting procedure in Sybyl-X.
