Abstract: Strategic use of a sequential Sonogashira coupling/intramolecular alkyne-carbonyl metathesis process for the synthesis of pyridine ring from 1-(2-haloaryl)-1\textit{H}-pyrrole-2-carbaldehydes allowed ready access to a diverse novel benzo-fused indolizines, pyrrolo[1,2-\textit{a}]quinolines, in good to excellent yields. As a hybrid structure of indolizine and quinoline, the resulting scaffold has an acyl substituent at C5 position, which is difficult to make by any other known approaches.

Introduction

Alkyne-carbonyl metathesis (ACM) is a synthetic transformation that \( \alpha,\beta \)-unsaturated carbonyl compounds arise from alkyne and carbonyl functional groups through a [2+2] cycloaddition and cycloreversion process.\(^1\) As the resulting \( \alpha,\beta \)-unsaturated carbonyl group is a highly versatile functionality, this reaction often provides an opportunity for domino processes by its being coupled with other subsequent reactions such as Nazarov cyclization and intramolecular aza-Michael addition.\(^2\) Another interesting feature of ACM is that it allows facile access to a number of carbo- and heterocycles when these two functional groups are appropriately linked (Scheme 1(a)). Indeed, construction of several ring systems such as cycloalkenone and chromenone was realized by this concept.\(^3\)

Scheme 1. Synthetic Approach to Indolizine via ACM

![Scheme 1](image-url)
In connection with our research interest on design and synthesis of novel indolizines with distinctive substitution pattern, we wish to employ intramolecular ACM reaction to gain access to a pyridine moiety of indolizine from pyrrole-2-carboxaldehydes possessing a suitably situated triple bond (Scheme 1(b)). For this purpose, we envisioned that 1-(2-iodoaryl)-1H-pyrrole-2-carbaldehydes would be converted to benzo-fused indolizines, pyrrolo[1,2-a]quinolines, through a sequential Sonogashira coupling/intramolecular ACM process (Scheme 1(c)). The resulting product 2 can be viewed as a hybrid structure of 7-acylindolizine and 4-acylquinoline, two important pharmacophores, which would be useful for biological screening. Previous syntheses of this skeleton have been disclosed in the literature. For example, Fürstner developed hydroarylation of alkyne-containing biaryl derivatives and Lautens applied palladium-catalyzed annulation of aryl heterocycles with strained alkenes to get access to this backbone, respectively. More recently, Wang reported the synthesis of pyrrolo[1,2-a]quinolines via Ce(III)-catalyzed [3+2] annulation of 2-alkylazaarenes with nitroolefins. Notably, while there are several methods which enable installation of aryl, alkyl, or acyl group at C4 site of this nucleus, construction of pyrrolo[1,2-a]quinolines bearing an acyl group at C5 position has been very rare.

Results and discussion

The required 1-(2-iodoaryl)-1H-pyrrole-2-carbaldehydes 1 for this study were prepared by adopting a procedure consisting of Paal-Knorr pyrrole synthesis and Vilsmeier Haack formylation (Scheme 2). Thus, acid-catalyzed reaction of 2-iodoaniline and 2,5-dimethoxytetrahydrofuran cleanly afforded the desired pyrrole 3a, which was converted to 4a along with 4a upon subsequent formylation. Sonogashira coupling reaction of 4a with
phenylacetylene occurred in acetonitrile as solvent at 70 °C, furnishing the coupled product 5a in 95.2% yield.

**Scheme 2. Synthesis of 5a**

5a A mixture of 2-iodoaniline (4.57 mmol), 2,5-dimethoxytetrahydrofuran (0.62 mL, 1.05 equiv), and AcOH (0.32 mL, 1.22 equiv) in DCE (8.5 mL) and H2O (5.0 mL) was heated at 80 °C. A mixture of 3a (3.72 mmol) and POCl3 (0.69 mL, 2.0 equiv) in DMF (4 mL) was stirred at rt. A mixture of 4a (0.4 mmol), phenylacetylene (0.049 mL, 1.1 equiv), (Ph3P)2PdCl2 (14 mg, 0.05 equiv), CuI (3.9 mg, 0.05 equiv), and Et3N (0.113 mL, 2.0 equiv) in CH3CN (1.5 mL) was heated at 70 °C.

Optimal conditions for ACM via exposure of 5a to several acidic media were then examined and the results are summarized in Table 1. When 5a was treated with either catalytic or stoichiometric amount of BF3-Et2O at rt, no reaction occurred (entries 1 and 2). Elevating the reaction temperature to 80 °C gave the desired product 6a in 30% yield while increasing the amount of BF3-Et2O to 1.5 equiv did not result in better chemical yield (entries 3 and 4). Use of other Lewis acids such as In(OTf)3, InCl3, or AgOTf provided the similar results (entries 5-7). To our delight, reaction of 5a in formic acid at 100 °C furnished 6a in 62% yield (entry...
Finally, we were pleased to find that the desired product was cleanly obtained under TFA at 90 °C (entry 9).

$^a$ A mixture of 5a (0.1 mmol) and catalyst in solvent (0.5 mL) was stirred at the indicated temperature and time unless otherwise noted. $^b$ Isolated yield (%). $^c$ Formic acid or TFA was used as solvent.

Formation of 6a from 5a can be rationalized based on the mechanism previously proposed (Scheme 3). Addition of TFA to the alkyne unit in 5a would generate A, which then undergoes intramolecular aldol/dehydration to give rise to 6a. Alternatively, it can be understood via alkyne addition to aldehyde promoted by initial protonation (B). Attack of the resulting carbocation by the neighboring hydroxyl group (C) followed by [2+2] cycloreversion (D) would lead to 6a.

Scheme 3. Proposed ACM Mechanism
Having established a new and efficient synthetic route to pyrrolo[1,2-a]quinoline skeleton by way of a sequential Sonogashira coupling/ACM procedure, we first examined the reaction scope by reacting 4a with several other alkynes (Scheme 4). Under optimized conditions, several alkynes were installed to afford the corresponding 5b-5j in good yields. Submission of the resulting coupled products 5b-5g to TFA led to the desired cyclized compounds 6b-6g in excellent yields (entries 1-6). Electron density of the aryl moiety in 5 did not seem to affect the reaction efficiency. ACM of substrate having a heteroaryl group such as thiophene proceeded well to give the corresponding product (entry 5). Using a mixture of TFA/DCE (1:1) provided better isolated yields in cases of 5d-5g than using neat TFA. However, exposure of cyclohexene-containing substrate 5h to these conditions provided 6h in low yield presumably due to decomposition of the product (entry 7). Unfortunately, little or no conversion was observed with compounds possessing a cyclopentyl or n-butyl group (entries 8 and 9).
Scheme 4. Synthesis of Diverse Pyrrolo[1,2-\textit{a}]quinolines via Reactions of 4a with Several Alkynes

A mixture of 4a (0.4 mmol), alkyne (1.1 equiv), (Ph$_3$P)$_2$PdCl$_2$ (14 mg, 0.05 equiv), CuI (3.9 mg, 0.05 equiv), and Et$_3$N (0.11 mL, 2.0 equiv) in CH$_3$CN (1.5 mL) was heated at 70 °C. A mixture of 5 (0.1 mmol) in TFA (0.5 mL) was stirred at 90 °C unless otherwise stated.

Isolated yield (%) $^c$ A mixture of 5 (0.1 mmol) in TFA/DCE (1:1, 1 mL) was stirred at 90 °C.

Generality of this reaction was further investigated by exposing several other 4b-4e to these conditions (Scheme 5). Irrespective of the electronic properties of iodoaryl rings, the whole sequence proceeded smoothly to give the products in good yields except for the cases of ACM reactions of substrates bearing a cyclohexene unit, 5o and 5t.

Scheme 5. Synthesis of Diverse Pyrrolo[1,2-\textit{a}]quinolines via Reactions of 4b-4e with Several Alkynes$^d$
In addition, the chemistry described above was applied to 2-bromo-4-methylaniline to expand the substrate scope (Scheme 6). Thus, 1-(2-bromo-4-methylphenyl)-1H-pyrrole-2-carbaldehyde 8 was prepared by following the similar procedure for 4a. Again, 8 underwent Sonogashira cross-coupling with phenylacetylene to furnish 5p in 82% yield.

In summary, we have accomplished a highly efficient synthesis of a novel benzo-fused indolizines, pyrrolo[1,2-α]quinolines, by way of a sequential Sonogashira cross-coupling/intramolecular alkyne-carbonyl metathesis process to construct the central pyridine ring. Several 1-(2-haloaryl)-1H-pyrrole-2-carbaldehydes readily prepared by way of Paal-Knorr pyrrole ring synthesis and subsequent Vilsmeier Haack formylation of commercially available 2-haloanilines were successfully converted to various pyrrolo[1,2-α]quinolines with an acyl substituent at C5 site, which cannot be accessed by any other synthetic methods. Unprecedented substitution pattern of this nucleus should be useful to explore its various biological functions. Application of this protocol for the synthesis of other heterocycles as well as investigation on utility of these compounds are currently in progress.

General Methods

Unless specified, all reagents and starting materials were purchased from commercial sources and used as received without purification. “Concentrated” refers to the removal of volatile solvents via distillation using a rotary evaporator. “Dried” refers to pouring onto, or passing through, anhydrous magnesium sulfate followed by filtration. Flash chromatography was performed using silica gel (230–400 mesh) with hexanes, ethyl acetate, and dichloromethane as eluent. All reactions were monitored by thin-layer chromatography on 0.25 mm silica plates (F-254) visualizing with UV light. $^1$H and $^{13}$C NMR spectra were recorded on 400 MHz NMR spectrometer and were described as chemical shifts, multiplicity (s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet), coupling constant in hertz (Hz), and number of protons. IR spectra were recorded on FT-IR using diamond ATR technique and were described as wavenumbers (cm$^{-1}$). HRMS were measured with electrospray ionization (ESI) and Q-TOF mass analyzer.

Representative Procedure for the Synthesis of 3a

To a stirred solution of 2-iodoaniline (1 g, 4.57 mmol), AcOH (0.32 mL, 1.22 equiv) and H$_2$O (5.0 mL) in DCE (8.5 mL) at 80 °C was added 2,5-dimethoxytetrahydrofuran (0.62 mL, 1.05 equiv) in one portion and heating was continued at 80 °C for 12 h. After cooling, layers were separated and the aqueous layer was extracted with CH$_2$Cl$_2$ (2 x 30 mL). The combined organic layer was dried over anhydrous MgSO$_4$ and concentrated under reduced pressure to afford the crude product which was purified by flash chromatography on silica gel (hexanes: EtOAc, 95:5) to furnish 3a as colorless oil (1.21 g, 98.5%).

**Representative Procedure for the Synthesis of 5a**

To a flask charged with 4a (0.12 g, 0.4 mmol), (PPh$_3$)$_2$PdCl$_2$ (0.014 g, 0.02 mmol), CuI (0.0039 g, 0.02 mmol) and phenyl acetylene (0.049 mL, 0.44 mmol) in acetonitrile (1.5 mL) was added Et$_3$N (0.113 mL, 0.8 mmol) at rt. After being stirred at 70 °C under nitrogen atmosphere for 12 h, the reaction mixture was concentrated in vacuo to yield the crude product, which was purified by flash chromatography on silica gel (hexanes: EtOAc, 9:1) to give 5a as an off white solid (0.104 g, 95.2%).

Representative Procedure for the Synthesis of 6

**Condition A**: In a vial containing 5a (27 mg, 0.1 mmol) was added TFA (0.5 mL) and the resulting solution was stirred at 90 °C for 1 h. The reaction mixture was cooled down to rt and concentrated \textit{in vacuo} to yield the crude product. Purification by flash chromatography on silica gel (hexanes: EtOAc, 95:5) gave 6a as a yellow solid (26.7 mg, 99%).

**Condition B**: In a vial containing 5d (30 mg, 0.105 mmol) was added DCE (0.5 mL) and TFA (0.5 mL) and the resulting solution was stirred at 90 °C for 1 h. The reaction mixture was cooled down to rt and concentrated \textit{in vacuo} to yield the crude product. Purification by flash chromatography on silica gel (hexanes: EtOAc, 95:5) gave 6d as a yellow solid (24.6 mg, 82%).
