Experimental

Synthesis of materials

For the electrospinning solution of SnO$_2$ nanotubes (NTs), 1 g of tin chloride dehydrate (SnCl$_2$·2H$_2$O, Sigma Aldrich), 5 g of ethanol (C$_2$H$_6$O, Merck) were mixed first and stirred for 2 h and 1.4 g of polyvinylpyrrolidone (M$_w$ = 1,300,000, PVP, Sigma Aldrich) and 5 g of N, N-dimethylformamide (DMF, Sigma Aldrich) were added and stirred for 4 h. Electrospinning was conducted under the following conditions: distance of 12 cm between the tip of the needle (25 gauge) and current collector, applied voltage of 15 kV, with a flow rate of 20 μl min$^{-1}$. As-spun Sn precursor/PVP nanofibers (NFs), then, were calcined at 600 °C for 1 h and 700 °C for 1 h at a heating rate of 10 °C min$^{-1}$ in a muffle furnace under air atmosphere, in order that SnO$_2$ NTs were formed. To carry out the sol-gel process of TiO$_2$ layer on top of SnO$_2$ NTs, 0.12 g of titanium butoxide (Ti[O(CH$_2$)$_3$CH$_3$]$_4$, Aldrich) and 0.12 g of de-ionized water (DIW) were mixed in 4.8 g of ethylene glycol (EG, Junsei Chemical) and 1.2 g of ethanol in the presence of 0.3 g of SnO$_2$ for 6 h at 80 °C. It was cleaned with ethanol two times by centrifugation at 3000 rpm for 15 min each. It was dried overnight (for 12 h) and thermally annealed at 550 °C for 1 h at a heating rate of 10 °C min$^{-1}$ in a muffle furnace under air atmosphere. This sample is denoted as SnO$_2$@TiO$_2$. For another sample with higher TiO$_2$ concentration, 0.4 g of titanium butoxide (Ti[O(CH$_2$)$_3$CH$_3$]$_4$, Aldrich) and 0.4 g of DIW were mixed in 3.2 g of ethylene glycol (EG, Junsei Chemical) and 0.8 g of ethanol in the presence of 0.2 g of SnO$_2$ for 6 h at 80 °C, under same centrifugation condition and subsequent drying and annealing process. This sample is denoted as SnO$_2$@TiO$_2$ (X5). To synthesize SnO$_2$@TiO$_2$ NTs wrapped by rGO sheets, 0.3 g of SnO$_2$@TiO$_2$ was mixed with 0.1 g of polyallylamine hydrochloride (PAH, M$_w$ = 15,000, Sigma Aldrich) for 2 h and centrifuged three times at 3000 rpm for 15 min each. It was dried for 12 h and stirred with 6 g of graphene oxide in
water solution (2 ml mg⁻¹, Sigma Aldrich) for 24 h. It was then mixed and stirred with 2 g of hydrazine monohydrate (64–65%, Sigma Aldrich) and dried for 12 h. This rGO-wrapped SnO₂@TiO₂ sample is denoted as SnO₂@TiO₂@rGO.

**Cell Assembly**
To carry out the electrochemical tests, cells were assembled in 2032 coin-type half cells. The anodes (SnO₂, SnO₂@TiO₂, and SnO₂@TiO₂@rGO NTs) were composed of active materials, super P carbon black, poly(acrylic acid)/sodium carboxymethyl cellulose (50/50 wt%/wt%, Aldrich) binder at a weight ratio of 80:10:10. They were slurry-casted on Cu current collector and dried in a vacuum at 150 °C for 2 h. The mass loading of active materials were ~ 2 mg cm⁻² for SnO₂, SnO₂@TiO₂, and SnO₂@TiO₂@rGO NTs. The 2032 coin-type half cells consisted of lithium metal as a counter electrode, a Celgard 2325 separator, and 1.3 M lithium hexafluorophosphate (LiPF₆) in ethylene carbonate/diethylene carbonate (EC/DEC, 3/7 v/v) with 10 wt% fluoroethylene carbonate (FEC) (PANAX ETEC.) for electrolytes. They were assembled in an Ar-filled glove box.

**Characterization**
As-spun Sn precursor/PVP NFs, SnO₂, SnO₂@TiO₂, and SnO₂@TiO₂@rGO NTs were characterized by a field emission scanning electron microscopy (FE-SEM, Nova 230, FEI) operating at 10 kV. Surface area of SnO₂@TiO₂ was measured using BET (Brunauer–Emmett–Teller) device (Tristar II 3020, Micromeritics). To characterize the morphologies of the SnO₂@TiO₂, SnO₂@TiO₂ (X5), and SnO₂@TiO₂@rGO, field emission electron microscopy (FE-TEM, Tecnai TF30 ST, FEI) operating at 300 kV was employed. The crystalline structure of SnO₂ and SnO₂@TiO₂ (X5) was analyzed with a powder
X-ray diffractometer (XRD, D/MAX-2500, Rigaku) using Cu Kα radiation ($\lambda=1.54$ Å) between 20° and 80° at a scan rate of 0.066 ° s$^{-1}$. The weight percentage of rGO in SnO$_2$@TiO$_2$@rGO was confirmed by thermogravimetry analyzer (TGA, TG 209 F3, NETZSCH). Raman spectra were obtained from dispersive Raman spectrometer (ARAMIS, Horiba Jobin Yvon) to investigate the characteristics of wrapped rGO layer in SnO$_2$@TiO$_2$@rGO using a He-Ne laser operating at $\lambda = 633$ nm. Surface state of SnO$_2$@TiO$_2$ and SnO$_2$@TiO$_2$@rGO was analyzed using X-ray photoelectron spectroscopy (XPS) (K-alpha, Thermo VG Scientific). The 2032 coin-type half cells were cycled at a current density of 100-5000 mA g$^{-1}$ between 0.01 and 3 V using battery testing device (Maccor Series 4000, KOREA THERMO-TECH). Cyclic voltammetry (CV) was conducted at 0.1 mV s$^{-1}$ within a range of 0.01 to 3.0 V using battery testing device (WBCS4000, Wonatech). Conductivity of SnO$_2$, SnO$_2$@TiO$_2$, and SnO$_2$@TiO$_2$@rGO NTs was examined by an AC impedance analyzer (ZIVE SP1, Wonatech).
