Supporting information

1. Experimental Section

1.1 Materials

Flake graphite and 20% Pt/C used in this study were purchased from Sigma-Aldrich. Cyclohexane (Sinopharm Chemical Reagent Co., Ltd) was freshly distilled before using. Ferrocene, aluminum, aluminum powder were purchased from Aladdin (Shanghai, China) and used without further purification.

1.2 Preparation of rGFeCp via ligand exchanging.

Graphene oxide (GO) was prepared from flake graphite by a modified Hummer’s method. More related literature on graphene preparation by chemical exfoliation, electrochemical exfoliation please see the reference. Reduced graphene oxide (rG) was prepared by hydrate reduction of GO in presence of sodium dodecylbenzenesulphonate. First, ferrocene (7.44 g, 40.0 mmol), AlCl3 (13.33 g, 100 mmol), Al powder (1.36 g, 50mmol), cyclohexane (500.0 mL), and rG (0.5 g) were added to a round bottom flask under inert atmosphere. The mixture was then heated to 80°C under vigorous stirring for 36h. After centrifugation and washed with methanol, acetone, and ether in turn and at last dried at 60°C under vacuum for 5h, iron (II) 1-cyclopenta-2,4-dienyl reduced graphene oxide (denoted as rGFeCp) was produced.

Iron (II) 1-cyclopenta-2,4-dienyl graphite (GFeCp) was prepared under the same condition as rGFeCp using graphite flake as starting material for comparison.

1.3 Pyrolysis and activation

rGFeCp was pyrolyzed at a heating rate of 5 °Cmin⁻¹ and held at the 800 °C for 2h under nitrogen flow. The obtained rGFe-800 was further activated under NH3 flow (30 ml/min) for 10 min under 800 °C to produce iron/nitrogen co-doped porous graphene (rGFe-800a). Similarly, GFe-800 and GFe-800a were prepared under the same procedure. Besides, rG was also activated under the same condition to produce nitrogen-doped graphene (rG-800a).

1.4 Characterization

Atomic force microscopy (AFM) images were obtained with a microscope MUL TIMODE NANOSCOPE (DI Co., USA). Transmission electron microscope (TEM) was performed on a JEOL-2100 (JEOL Ltd., Japan) electron microscope operated at an acceleration voltage of 200kV. Scanning electron microscopy (SEM) was carried out with an FEI Sirion-200 (FEI Co., USA). Thermogravimetric analysis (TGA) of the samples(S1) was undertaken using a Q5000IR (TA Instruments, USA) thermogravimetric analyzer with a heating rate of 20°C min⁻¹ from room temperature up to 800°C under nitrogen flow. Fourier transform infrared spectroscopy (FT-IR) was performed on a Spectrum 100 (Perkin Elmer, Inc., USA) spectrometer with a scan range of 4000-400 cm⁻¹. Raman measurements were recorded on an InVia/Reflex Lasser Micro-Raman spectroscope (Renishaw, England) with excitation laser beam wavelength of 532 nm. The powders were placed on a clean glass substrate that was
used for the Raman measurement. X-ray photoelectron spectra (XPS) were determined by an AXIS Ultra DLD system (Kratos Co., Japan) using Al Ka radiation as the X-ray source.

1.5 Electrochemical measurements

All the electrochemical measurements including cyclic voltammetry (CV), rotating disk electrode (RDE) measurements and rotating ring disk electrode (RRDE) were carried out in a conventional three-electrode cell and O₂-saturated 0.1 M KOH solution using AFMSRCE2759 electrochemical system (Pine Instrument Co., USA) at room temperature. Reference and counter electrodes are Ag/AgCl and platinum wire, respectively. A RRDE electrode with a Pt ring and a glassy carbon disk loading the electrocatalyst was used as the working electrode. The electrocatalyst sample was synthesized as follows: 5mg catalyst was dissolved in 500µL of 0.25% Nafion ethanol solution, and then stirred overnight to form homogeneous solution. 10µL of the solution was pipetted onto glassy carbon electrode which has a diameter of 5.61 mm, leading to a catalyst loading of 0.6 mg/cm². The solution was dried in the air and ultimately a sample film was formed on the glassy carbon surface. In order to measure for comparison, a working electrode loaded commercial 20wt.% platinum was prepared with the same procedure as above except adding 2 mg of Pt/C (20wt.%Pt) into 500ml 0.25% Nafion ethanol solution. After that, CV was conducted under alkaline condition (N₂- and O₂-saturated 0.1 M KOH as well as O₂-saturated 0.1 M KOH solution with 1.0 M methanol) to test the electric catalytic properties of the materials. The voltage range was set between -1.0 to 0 V with a scan rate of 100 mV s⁻¹ at room temperature after bubbling O₂ or N₂ for 30 min.

For the RDE measurements, catalyst inks were prepared by the same method as CV’s. The working electrode was scanned cathodically at a rate of 10 mV s⁻¹ with a varying rotating speed of 225-1600 rpm. Koutecky–Levich plots following of the main text were analyzed at various electrode potentials. The number of electrons transferred (n) was calculated from the slopes of their best linear fit lines.\(^5\)

\[
1/J = 1/J_L + 1/J_K = 1/Bo^{0.5} + 1/J_K \quad (1)
\]

\[
B = 0.62nFC_o(D_o)^{-1/6} \quad (2)
\]

\[
J_K = nFkC_o \quad (3)
\]

Where \(J\) is the measured current density, \(J_K\) and \(J_L\) are the kinetic- and diffusion-limiting current densities, \(\omega\) is the angular velocity, \(n\) is transferred electron number, \(F\) is the Faraday constant (96 486 C cm⁻²), \(C_o\) is the bulk concentration of O₂(\(C_o = 1.2 \times 10^{-3}\) mol L⁻¹), \(\nu\) is the kinematic viscosity of the electrolyte (0.01 cm² s⁻¹), and \(k\) is the electron-transfer rate constant.

For the RRDE measurements, catalyst inks and electrodes were also prepared by the same method as CV’s. The disk electrode was scanned cathodically at a rate of 10 mV s⁻¹, and the ring potential was constant at 0.5 V. Based on the RRDE result, the electron transfer number (\(n\)) and the \(HO_2^-\) concentration (%) were calculated by the following equations:

\[
n = 4I_D/(I_D + I_R/N) \quad (4)
\]
\[ \% (\text{HO}_2^-) = \frac{200I_R/N}{(I_D + I_R/N)} \] (5)

Where \( I_D \) and \( I_R \) are the disk and ring currents, respectively, and \( N = 0.37 \) is the ring collection efficiency.\(^5,6\)
