Calculations. The volumetric capacitance ($C_v$) of the electrodes was calculated through the following equation:

$$C_v = \frac{I\Delta t}{V\Delta E}$$

where $I$ is the discharge current, $\Delta t$ is the discharge time, $\Delta E$ is the potential window during
the discharge process (after IR drop), and \( V \) is the effective volume of the carbon fiber electrode.

\( C_v \) of the electrodes could be also calculated from the CV curves using the following equation (2):

\[
C_v = \frac{A}{2Vs\Delta E}
\]

(2)

where \( A \) is the area of the CV curve and \( s \) is the scan rate.

Volumetric energy density \( (E_v) \) and power density \( (P_v) \) of the SC device are calculated by following equations:

\[
E_v = 0.5C_d(\Delta U)^2/V_d
\]

(3)

\[
P_v = \frac{E_v}{\Delta t}
\]

(4)

where \( C_d \) is the capacitance of the SC device, \( V_d \) is the volume of the SC device, \( \Delta U \) is the operating voltage of the SC device and \( \Delta t \) is the discharging time.
