Experimental procedures:

Synthesis of TiO₂ paste. 10~20 nm anatase-TiO₂ nanoparticles were synthesized via a hydrothermal approach reported elsewhere with some modifications.1-2 Typically, 19.9 g titanium (IV) isopropoxide was mixed with 4.2 g acetic acid and stirred at room temperature for 15 min. Then the mixed solution was poured into 101 mL deionized water and stirred for 60 min at room temperature with a rate of 1000 rpm. Next, 1.4 mL 65% nitric acid (HNO₃) was added to the solution and stirred for 40 min, followed by reflux at 80 °C for further 60 min. 20 mL deionized water was then added, before transferring all of the solution to Teflon reactors in an oven held at 250 °C for 12 h. After cooling to room temperature, 0.84 mL 65% HNO₃ was added, followed treated with a 40 W ultrasonic probe at frequency of 60 pulses every 2 s. The resultant solution was centrifuged at 7500 rpm and rinsed with water for three
times. Centrifugation and rinsing were repeated three more times with ethanol before a white precipitate containing 40 wt% TiO$_2$ in absolute ethanol was obtained. 0.72 g ethyl cellulose, 0.14 g lauric acid, and 7.2 g terpineol were added into the 3.75 g 40 wt% ethanol solution of TiO$_2$ particles, and then the ethanol was removed from the solution employing a rotary evaporator to prepare viscous TiO$_2$ pastes.

**Synthesis of TiO$_2$-coated FTO substrates.** FTO-coated glass substrates were etched with Zn powder and 37% HCl to obtain the required pattern. The etched FTO substrates were then cleaned by hellmanex detergent, deionized water, acetone, isopropanol and ethanol respectively, followed by drying with N$_2$ blow. The clean FTO substrates were coated with a TiO$_2$ blocking layer through spin-coating a 0.15 M titanium diisopropoxide bis(acetylacetonate) (75 wt% in isopropanol) in 1-butanol at 2000 rpm for 40 s, followed by heating at 125 °C for 5 min. After cooling to room temperature, a diluted TiO$_2$ paste solution (0.12 g TiO$_2$ paste in 1 mL ethanol) was spin-coated on the TiO$_2$ blocking layer at 2000 rpm for 10 s, and dried at 120 °C for 10 min. After that, the resultant substrates were annealed at 550 °C for 30 min, providing a thickness of 130−150 nm (Fig. S1). The mesoporous TiO$_2$ films were immersed in a 0.04 M aqueous TiCl$_4$ solution at 90 °C for 10 min. After washing with deionized water, the films were annealed at 550 °C for 20 min to obtain the TiO$_2$-coated FTO substrates for perovskite deposition.

Synthesis of organometal halide perovskite precursor solution. Perovskite precursors were prepared according to the reported procedure with some modifications. Typically, 36 mL methylamine (CH$_3$NH$_2$) (33 wt% in absolute ethanol) was reacted with 15 mL hydroiodic acid (HI) (57 wt% in water) with stirring at 0 °C for about 2 h to synthesize methylammonium iodide (CH$_3$NH$_3$I). Crystallization of CH$_3$NH$_3$I was achieved using a rotary evaporator at 60 °C for 2~3 h. The obtained CH$_3$NH$_3$I powder was washed with diethyl ether and dried in a vacuum oven at 50~60 °C for 24 h. PbI$_2$ was prepared as yellow precipitate by mixing solutions of 0.05 mole (16.56 g) Pb(NO$_3$)$_2$ and 0.1 mole (16.6 g) KI, followed by drying in a vacuum oven at 50~60 °C for 24 h. 1.6 M clear perovskite precursor solution was obtained by mixing 3.688 g PbI$_2$ and 1.272 g CH$_3$NH$_3$I in a mixed solvent containing 5 mL DMF and 600 μL DMSO at room temperature with stirring for 15~30 min.

Dark-blue mirror-like perovskite thin film fabrication. Dark-blue mirror-like perovskite films were prepared by the solvent-treated two-step spin-coating method. First, 100 μL clear perovskite solution (1.6 M) was spin-coated on the surface of the TiO$_2$-coated FTO substrate (active area 1*1.5 cm$^2$) at 2000 rpm for 15 s (the first-step process). After the substrate was completely frozen, 1.5 mL nonpolar solvent (e.g. diethyl ether, toluene, chloroform, dichloromethane, chlorobenzene, and n-butanol, typically diethyl ether for the best device performance and reproducibility) was immediately spread over the substrate to wash the as-prepared film within 3~5 s. Then the substrate was accelerated again to get rid of the excess solvent left in the nonpolar solvent scouring process and spun at 5000 rpm for 20 s, resulting in a transparent film formed on the substrate (the second-step process). The resultant film was heated at 100 °C for 2 min to synthesize dark-blue mirror-like perovskite film. The procedure of the spin-coater is summarized in Fig. S2. Dark-blue mirror-like perovskite films with different thicknesses were obtained by employing different rotation speeds (4000, 5000, and 6000 rpm) in the second-step spin-coating process to investigate the effect of the film thickness on the absorption and the photovoltaic
performances.

Fig. S2 Procedure of the spin-coater in the solvent-treated two-step spin-coating method.

Dark-brown perovskite thin film fabrication. Dark-brown perovskite films were prepared by the conventional solvent engineering one-step spin-coating process, where the nonpolar solvent is added to the substrate while spinning. Typically, 100 μL perovskite solution was dropped onto the TiO₂-coated FTO substrate (active area 1*1.5 cm²). The substrate was then spun at 5000 rpm for 35 s and 1.5 mL diethyl ether was quickly dropped onto the center of the spinning substrate within 5 s. Dark-brown perovskite film was prepared by heating the resultant film at 100 °C for 2 min. The procedure of the spin-coater is summarized in Fig. S3. Dark-brown perovskite films with different thicknesses were obtained by employing different rotation speeds (3000, 4000, and 5000 rpm) in the spin-coating process to investigate the effect of the film thickness on the absorption and the photovoltaic performances.
Solar cell fabrication. The as-prepared perovskite films were spin-coated with a 2,2',7,7'-tetrakis-(N,N-di-p-methoxyphenyl-amine)-9,9'-spirobifluorene (spiro-MeOTAD) solution at 4000 rpm for 20 s, which was obtained by dissolving 73 mg spiro-MeOTAD in 1 mL chlorobenzene, 29 μL 4-tert-butyl pyridine (TBP) and 18 μL lithium bis(trifluoromethanesulfonyl)imide (Li-TFSI) (520 mg Li-TFSI in 1 mL acetonitrile) solution. Finally, a 100~150 nm Au layer was thermally evaporated on the spiro-MeOTAD layer as counter electrode.

Characterizations. The morphologies of the synthesized perovskite films were characterized by a field emission scanning electron microscope (Zeiss Supra-55) operated at 10 kV and an optical microscope (Olympus BX51). Statistical histograms of the pinhole sizes were summarized from the optical microscopic images with magnification of 50 X. AFM characterizations were performed using a Bruker Innova in tapping mode. The AFM images were measured by scanning over a range of 15*15 μm² at a resolution of 256*256 data points. The thicknesses of the TiO₂ films and the
synthesized perovskite films were characterized by a Stylus Profiler (Bruker Dektak XT) and confirmed by cross-sectional SEM images. X-ray diffraction (XRD) patterns of the samples were obtained using a diffractometer (Rigaku RINT2000 X-Ray) with Cu Kα radiation at a scan rate of 4° min⁻¹ under operation condition of 50 kV and 80 mA. Ultraviolet-visible diffuse absorption spectra were recorded on a spectrophotometer (Hitachi U3900) in 450~850 nm wavelength at room temperature. Photoluminescence (PL) spectra were obtained by an optical spectrometer system (Horiba HR Evolution) with a 50 mW laser (λ = 532 nm) as excitation source. Fabricated photovoltaic cells were characterized by incident photon-to-current conversion efficiency (IPCE) and current-voltage (J-V) tests in air. The IPCE values were measured by an EQE system (Oriel IQE200) under DC mode, where a 300 W Xenon lamp was used as the light source for generating monochromatic beam. The J-V curves of the photovoltaic cells were measured under AM 1.5 G one sun illumination (100 mW cm⁻²) with a solar simulator (Newport 94021A), a source meter (Keithley 4200), and a calibrated Si-reference cell certified by NREL. The J-V curves were recorded by forward (from short-circuit to open-circuit) and reverse (from open-circuit to short-circuit) modes with a scan rate of 10 mV s⁻¹ and a delay time of 40 ms. All devices were measured by masking the active area with a shadow mask (0.196 cm² in area) and placed in the dark prior to the start of the measurement without any voltage applied both for the reverse and forward scans.
