**Reagents, measurements, and characterizations.** All chemicals and solvents were reagent grades and purchased from ACROS, Aldrich, TCI, Fluka, and TEDIA. THF was distilled over sodium/benzophenone to keep anhydrous before use. After distillation over CaH₂, DMF was purified by refluxing with calcium hydride and then distilled. The solvents were degassed by nitrogen 1 h prior to use before reaction. ¹H-NMR spectra were recorded on a Bruker DX-300 (300 MHz for ¹H) spectrometer using CDCl₃, and DMSO-d₆ solvents. Elemental analyses were performed on HERAEUS CHN-OS RAPID elemental analyser. The phase transition properties of monomers and polymers were studied by polarizing optical microscopy (POM) using a Leica DMLP equipped with a temperature control hot stage (Mettler Toledo FP82HT) upon cooling process (cooling rate 0.5°C/min⁻¹). Temperatures and enthalpies of phase transitions were determined by differential scanning calorimetry (DSC, model: Perkin Elmer Pyris 7) under N₂ upon the first cooling and second heating cycles at a rate of 1°C/min⁻¹. The molecular weights of polymers were obtained via gel permeation chromatography (GPC) measurements, which were carried out at 40°C on a Waters 1515 instrument equipped with three Waters μ-Styrage columns (103, 104 and 105 Å) in series and a RI detector (ERMA Inc., ERC-7522). All GPC data were acquired by using tetrahydrofuran (THF) as the eluent at a flow rate of 1.0 mL/min and polystyrene samples as the molecular weight standards. The AFM images were observed by an atomic-force microscope (AFM, Veeco diInnova, scanning rate 0.5 to 1 Hz).

General synthetic procedures of homopolymers and copolymers.

All of the polymerizations were carried out by the free radical polymerization described as follows: To a Schlenk tube, monomers M1 and M2 were mixed with appropriate molar ratios (0:10, 9:1, 3:7, 5:5, 7:3, 1:9 and 10:0) dissolved in dry chlorobenzen (0.146 M) and AIBN (0.03 e.q) as an initiator. The solution was degassed by three freeze-pump-thaw cycles and then sealed off. The reaction mixture was stirred and
heated at 60°C for 24 h. After polymerization, the polymer was precipitated into diethyl ether for homo- and co-polymers. The precipitated polymers were collected, washed with diethyl ether, and dried under high vacuum.

Fig. S1 $^1$HNMR spectra of (a) M1/M2(5/5) and (b) P12(soln:5/5) in CDCl$_3$. The copolymer composition of P12(soln:5/5) was estimated by comparing with M1/M2(5/5) after solution polymerization with the relative integration areas of the peaks at 0.5-2.0 ppm as 3 protons (i.e., the vinyl acrylate group). This result indicated that the feed-in and output molar ratios were almost consistent. The compositions of all copolymers were all evaluated by this method.
