Supplemental methods

1. **Synthesis of mPECT**

mPECT was prepared by a ring-opening copolymerization of CL and TOSUO as reported previously using mPEG$_{2k}$ as macroinitiator and stannous octoate as catalyst. A typical mPECT copolymer was synthesized as follows: 7.82 g (68.6 mmol) of ε-CL, 1.179 g (6.85 mmol) of TOSUO, 3.0 g (5.45 mmol) of mPEG$_{2k}$, and 0.06 g of Sn(Oct)$_2$ (0.5 wt.% of total reactants) were added into a reaction vessel under dry nitrogen atmosphere, and the reaction system was kept at 130 °C for 12 h. The product of reaction was first dissolved in methylene chloride, and then added dropwise into excess cold diethyl ether to precipitate mPECT. After filtering, mPECT was dried at room temperature under vacuum until a constant weight was obtained (yield: 90.5%).

$^a$ Y means could form hydrogel and N means not.
The solid content of NPs was 25 wt%, CD concentrations were 6 wt% in all mixtures were listed in table.
