1) General Information

Solvents and reagents were obtained from commercial sources and used without further purification. Spectroscopic grade DMF and DMSO were dried with 3 Å molecular sieves according to a reported procedure. Rhodamine 6G (Rh-6G) (dye content ~ 95%) was purchased from Sigma Aldrich. Proton NMR spectra were recorded on a Bruker Avance 300 MHz spectrometer and 600 MHz spectrometer in CDCl₃ solution with internal solvent signal peak at 7.26 ppm. Carbon NMR were recorded at 75 MHz spectrometer and 151 MHz spectrometer in CDCl₃ solution and referenced to the internal solvent signal at 77.26 ppm. Proton NMR data are reported as follows: chemical shift (ppm), multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, quint = quintet, dd = doublet of doublets, ddd = doublet of doublet of doublets, td = triplet of doublets, qd = quartet of doublets, m = multiplet, br. s. = broad singlet), and coupling constants (Hz). High resolution mass spectra (HRMS) were obtained from the central analytic mass spectrometry facilities of the Faculty of Chemistry and Pharmacy, Regensburg University and are reported according to the IUPAC recommendations 2013. All reactions were monitored by thin-layer chromatography using Merck silica gel plates 60 F254; visualization was accomplished with short wave length UV light (254 nm). UV–Vis and fluorescence measurements were performed with Varian Cary 50 UV/Vis spectrophotometer and FluoroMax-4 spectrofluorometer, respectively. Electrochemical studies were carried out under argon atmosphere. The measurements were performed in dimethylformamide (DMF) containing 0.1 M tetra-n-butylammonium tetrafluoroborate using ferrocene/ferrocenium (Fc/Fc⁺) as an internal reference. A glassy carbon electrode (working electrode), platinum wire counter electrode, and Ag quasi-reference electrode were employed. Spectroelectrochemical studies were carried out in an optically transparent thin layer electrochemical cell (OTTLE). Standard flash chromatography was performed using silica gel of particle size 40–63 μm. Photoreduction and annulation reactions were performed with 455 nm LEDs (OSRAM Osloan SSL 80 royal-blue LEDs (λ = 455 nm (± 15 nm), 3.5 V, 700 mA).

2) General Procedures

Synthesis of Starting materials:

Procedure for the synthesis of N-Aryl Pyrroles:

N-Aryl Pyrroles 1(a-c, e and f) were prepared by Paal-Knorr synthesis from the respective aniline, according to the procedure reported by Lee et al.²

**General Method:** A solution of aniline (1 equiv.) and acetic acid (0.07 mL/mmol aniline) in DCE (1.86 mL/mmol aniline) and water (1.12 mL/mmol aniline) were heated to 80°C. 2,5-Dimethoxytetrahydrofuran (1.05 equiv.) was then added in one portion and the heating was continued at 80°C overnight. Once cooled, the layers were separated and the aqueous layer was extracted with DCM. The combined organic layers were then dried with MgSO₄, filtered, and the solvent was removed in vacuo to yield the crude pyrrole.

3) General procedure for C–H arylation followed by intramolecular cyclization reactions:

In a 5 mL snap vial with magnetic stirring bar the aryl halide (0.1 mmol, 1.0 equiv.), the corresponding alkyne (20.0 equiv.) and Rh-6G (0.01 mmol, 0.2 equiv.) were added and the mixture was degassed by “pump-freeze-thaw” cycles (×3) via a syringe needle. DIPEA (2.2 equiv.) and dry DMSO (total volume of the solution 1.5 mL), were added under N2 and the resulting mixture was again degassed twice by syringe needle. This reaction mixture was transferred into a microreactor (capacity 1.7mL) and irradiated with blue light (455nm) under nitrogen at 25° C. The reaction progress was monitored by GC analysis. After 2.5 h to 24 h of irradiation, the reaction mixture was transferred to separating funnel, diluted with ethyl acetate and washed with 15 mL of water. The aqueous layer was washed three times (3 × 15 mL) with ethyl acetate. The combined organic phases were dried over MgSO4, filtered and concentrated in vacuum. Purification of the crude product was achieved by flash column chromatography using petrol ether/ethyl acetate as eluent.
Glass microreactors and irradiation setup used for photocatalysis:

The reaction mixture (1.5mL) was injected by syringe into the glass microreactor (LTF, 11×5.7cm×1.7mL internal volume, 0.3 mL volume of the reactor tubing) previously flushed with nitrogen. The flow reactor was cooled down to 25°C with a custom-made aluminum cooling block placed opposite to LEDs with a mirror to minimize loss of the light.
