Experimental Materials.

Methyl acrylate (MA, Alfa Aesar, 99%), Ethyl Vinyl Ketone (EVK, Alfa Aesar, 97%) were purified by passing through a neutral alumina column and distilled under reduced pressure to remove the inhibitor. N,N-dimethylacrylamide (DMA, Alfa, 99.5%) were distilled under reduced pressure and stored in the refrigerator before use.

Potassium peroxymonosulfate (Oxone®, Alfa), Methanol (J&K, 99.9%), toluene (Sinopharm Chemical Reagent Co., Ltd, 99.8%) were used as received.

Synthesis of the catalyst.

Organo-cobalt porphyrin complex (TMPCo-CO$_2$CH$_3$) was synthesized according to previous reported method.$^{[1]}$

Light Source.

A 500 W xenon lamp (CEL-S500, Aulight, Beijing, China) was used as the light source with a 420−780 nm filter to give visible light. The intensity of visible light irradiation was measured by a FZ-A radiometer (Photoelectric Instrument Factory of Beijing Normal University) equipped with a 400-1000 nm sensor.

Typical Procedure for Visible Light Initiated Polymerization.

A typical procedure for polymerization of vinyl ketones mediated by organo-cobalt complex is as follows: (1) a certain amount of TMPCo-CO$_2$CH$_3$ and monomers were mixed in C$_6$D$_6$or DMSO-d$_6$in a J. Young valve NMR tube; (2) after being thoroughly mixed and three freeze−pump−thaw cycles, the sample was refilled with nitrogen; (3) the sample was placed in a water bath at room temperature and irradiated for a period of time. The progress of polymerization was followed by $^1$H NMR measurement. When desired conversion (benzaldehyde sealed in capillary tube was used as external
reference) was reached, the reaction was stopped by exposure to air. The solvent and excess monomers were removed under vacuum. The resulting product without further purification was dissolved in DMF for GPC analysis.

**Coordination experiments**

(TMP)CoCOOMe (6.67 mM in C₆D₆) and the mixture solution of (TMP)CoCOOMe (6.67 mM in C₆D₆) and EVK (6.67 mM in C₆D₆) were detected by ¹H NMR respectively (Fig. S1, A, B). ¹H NMR results showed no change in both chemical shift and integral of each resonances of (TMP)CoCOOMe, indicating that the existence of EVK led to insignificant coordination to (TMP)CoCOOMe. Moreover, the resonances of (TMP)CoCOOMe still stayed the same even after 8 hours (Fig. S1, C). In addition, the signals of the remained (TMP)CoCOOMe (Fig. S1, D) after removing the EVK by reduced pressure distillation was the same as that of the initial (TMP)CoCOOMe (Fig. S1, A), which further confirmed that there is no interaction between (TMP)CoCOOMe and EVK.

**Fig S1.** From bottom to top: ¹H NMR of (TMP)CoCOOMe (6.67 mM in C₆D₆); ¹H NMR of the mixture solution of (TMP)CoCOOMe (6.67 mM in C₆D₆) and EVK (6.67 mM in C₆D₆); ¹H NMR of the mixture solution of (TMP)CoCOOMe (6.67 mM in C₆D₆) and EVK (6.67 mM in C₆D₆) after 8 hours; ¹H NMR of the remained (TMP)CoCOOMe after removing the EVK.
Synthesis of Block Copolymers.

Block copolymers were synthesized by sequential polymerization of EVK, MA and DMA. PEVK macroinitiators were synthesized by visible light initiated polymerization of EVK mediated by TMPCo-CO$_2$CH$_3$at 25°C. After a desired conversion was obtained, the resulting PEVK was used as macroinitiator for next DMA under variable conditions. After desired condition was reached, the polymerization was stopped. Solvent and excess DMA was removed under vacuum. The resulting PEVK-b-PDMA block copolymers were dissolved in DMF for GPC analysis without purification. Other block copolymers were obtained similarly.

Characterization.

Conversions of monomers were determined by $^1$H NMR spectrometry on a Bruker 400 MHz FT spectrometer in C$_6$D$_6$. $^1$H NMR spectrums of the block copolymers were recorded on a Bruker 400 MHz FT spectrometer in DMSO-d$_6$.

Gel permeation chromatography (GPC) was performed in Agilent 1200 series system, equipped with two VARIAN PolarGel-M columns (300 × 7.5 mm), an Iso Pump (G1310A), a UV detector at 420 nm, and a differential refractive index detector (RID). The number-average molecular weight ($M_n$), weight-average molecular weight ($M_w$), and the polydispersity (PDI) were measured in DMF at 50 °C with a flow rate of 1.0 mL/min. A series of poly(methyl methacrylate)s (molecular weight range of 2710–679 000 g/mol, from Polymer Laboratories) were used as standards for calibration.
