Experimental details

1.1 Chemicals and Materials

4-hydroxybenzaldehyde (98%), tert-butyl bromoacetate (98%), trifluoroacetic acid (99%), sodium metavanadate (99.9%), n,n’-dicyclohexylcarbodiimide, 4-dimethylaminopyridine and sarcosine (99%) were purchased from Aladdin. C₆₀ (99.5%) was purchased from Suzhou Dade Carbon Nanotechnology Co., Ltd. Sodium tungstate dihydrate (99.5%), phosphoric acid (85%), potassium chloride (99.5%), bromine (99.5%), potassium bicarbonate (99.5%), hydrogen chloride (36.0%–38.0%), sodium perchlorate monohydrate (99%), sodium carbonate anhydrous (99.8%) and sodium chloride (99.5%) were purchased from Sinopharm Chemical Reagent Co., Ltd. Deionized water was obtained from a water purification system (Ulupure Instrument Co. Ltd). All chemicals were used as received. Solvents used are of analytical grade and were purchased from Tianjin Fu Yu chemical co., LTD (China).

1.2 Syntheses

1.2.1 Synthesis of tert-butyl 2-(4-formylphenoxy) acetate

To a 100 mL two-neck flask, 1.2048 g (9.87 mmol) 4-hydroxybenzaldehyde and 2.0524 g (14.88 mmol) K₂CO₃ were added. After removing the air by repeated vacuum-argon cycles (×3), 20 mL anhydrous DMF was injected and the mixture was stirred at room temperature to make a homogeneous suspension. Then, 20 mL anhydrous DMF with pre-dissolved 2.4903 g (12.84 mmol) tert-butyl bromoacetate was injected and the mixture was stirred at 70 °C overnight. After cooled to room temperature, excess K₂CO₃ was removed by filtration and the mixture was concentrated under vacuum. The residue was dissolved in ethyl acetate, washed successively with water (×3) and brine (×1). The organic layer was combined, dried over anhydrous Na₂SO₄, and concentrated under
reduced pressure. The crude product was subjected to silica gel column chromatography using hexane/ethyl acetate (70/30 v/v) mixture as the eluent. The final product was obtained as a yellowish solid. (1.63 g, yield: 70.0% based on the conversion of 4-hydroxybenzaldehyde). ¹H NMR (400 MHz, CDCl₃): δ 9.90 (s, 1H, a), 7.87-7.82 (m, 2H, b), 7.02-6.98 (m, 2H, c), 4.60 (s, 2H, d), 1.46 (s, 9H, e). ESI-MS Calculated: 236.10; Found [M+H]^+: 237.11.

1.2.2 Synthesis of tert-butyl 2-(4-(1-methylfulleropyrrolidin-2-yl)phenoxy)acetate

To a 2L two-neck round bottom flask, 1.8326 g C₆₀ (2.54 mmol) and 0.7569 g sarcosine (8.50 mmol) were added. After removing the air by repeated vacuum-argon cycles (×3), 600 mL chlorobenzene was injected to make a homogeneous suspension. Then, 200 mL chlorobenzene containing 0.4001 g (1.69 mmol) tert-butyl 2-(4-formylphenoxy) acetate was injected and the mixture was stirred at 140 °C overnight. After cooled to room temperature, excess sarcosine was removed by filtration and the organic solvent was removed under reduced pressure. The residue was dissolved in toluene/ethyl acetate (80/20 v/v) and passed through a short silica gel column. The effluent was combined, concentrated under reduced pressure and redissolved in toluene. Further purification by gel permeation chromatography (GPC, Bio-Beads S-X1, 200-400 mesh) using toluene as an eluent afforded tert-butyl 2-(4-(1-methylfulleropyrrolidin-2-yl)phenoxy)acetate as a brown solid (0.922 g, yield: 55.4% based on the conversion of tert-butyl 2-(4-formylphenoxy) acetate, and 36.9% based on the conversion of C₆₀). ¹H NMR (400MHz, CDCl₃): δ 7.74-7.71 (m, 2H, a), 6.97-6.94 (m, 2H, b), 4.99-4.96 (d, 1H, J = 12.8 Hz, c), 4.89 (s, 1H, d), 4.52 (s, 2H, e), 4.26-4.23 (d, 1H, J = 12.8 Hz, e) 2.79 (s, 3H, f), 1.43 (s, 9H, g). MALDI-TOF-MS calculated: 983.15,
1.2.3 Synthesis of 2-(4-(1-methylfulleropyrrolidin-2-yl)phenoxy)acetic acid (C$_{60}$-COOH, 1a).

1a was obtained by hydrolysis of its carboxylic ester (tert-butyl 2-(4-(1-methylfulleropyrrolidin-2-yl)phenoxy)acetate, 1a$''$). 0.9220 g 1a$''$ was dissolved in dichloromethane/CF$_3$COOH (4/1, v/v) and was stirred for 24 h at room temperature. After concentrated under reduced pressure and dried in vacuum, 1a was obtained as a brown solid (0.8610 g, yield 93.38%). 1H NMR (400MHz, CDCl$_3$):

$\delta$ 10.06 (s, 1H, g), 7.81-7.80 (m, 2H, a), 7.03-7.01 (m, 2H, b), 5.21-5.18 (d, 1H, J = 12.8 Hz, c), 5.05 (s, 1H, d), 4.68 (s, 2H, e), 4.34-4.31 (d, 1H, J = 12.8 Hz, c) 2.89 (s, 3H, f). MALDI-TOF-MS calculated: 927.09, Found: 927.01.

1.2.4 Synthesis of (Bu$_4$N$^+$)$_6$[P$_2$W$_{15}$V$_3$O$_{59}$(OCH$_2$)$_3$CNH$_2$] (Dawson-NH$_2$, 1b)

1b was synthesized according to the literature procedures.$^{1-3}$ Measurements of $^1$H NMR, MALDI-TOF-MS and elemental analysis are consistent with literature results. $^1$H NMR (400 MHz, d$_6$-DMSO): $\delta$ 8.36 (s, 2H), 5.39 (s, 2H), 3.20-3.15 (m, 48H), 1.62-1.54 (m, 49H), 1.37-1.28 (m, 49H), 0.96-0.92 (m, 74H). $^{31}$P NMR (400MHz, d$_6$-DMSO): $\delta$ -7.62 (s, 1P), -13.68 (s, 1P). MALDI-TOF-MS calculated: 5489.50, Found: 5484.00.

1.2.5 Synthesis of the C$_{60}$-Dawson molecular Janus particle (I).
To a 500 mL two-neck round bottom flask, 0.2992 g 1a (0.32 mmol), 0.0680 g DCC (0.33 mmol) and 0.0399 g DMAP (0.33 mmol) was added. After removing the air by repeated vacuum-argon cycles (×3), 200 mL THF/CH$_3$CN (7/1, v/v) was injected to make a homogeneous suspension. After stirred for 1h at 45 °C, 100 mL THF/CH$_3$CN (7/1, v/v) containing 1.4056 g 1b (0.26 mmol) was injected. After stirred at 45 °C for 7 days, the mixture was filtered to remove the insoluble byproducts. The solvent was removed under reduced pressure and THF was added. The mixture was filtered and the filtrate which contains unreacted 1a was discarded. The so-obtained brown solid was dissolved in CH$_3$CN to get a dark-brown solution, which was then added dropwise to an excess of diethyl ether with vigorous stirring. The brown precipitates were collected and recrystallized from CH$_3$CN/diethyl ether. After thoroughly washed by acetone followed by drying for 24 h under vacuum, 1 was obtained as a dark-brown solid (0.2669 g, yield: 12.96% based on the conversion of 1a and 16.28% based on the conversion of 1b). Other amide coupling reagent such as EEDQ has also been tried. The phenomena observed during the reactions are quite similar. However, in this case we did not perform deep characterizations on the final product.

1.3 Characterizations

**Structural Analysis** NMR spectra were recorded on a BrukerAvance 400 spectrometer (Bruker, Germany) or an Agilent 600 spectrometer (Agilent, America). ESI-MS spectra were recorded on a Q-TOF6510 spectrograph (Agilent, USA). MALDI-TOF MS were recorded on a AXIMA Confidence TM mass spectrometer (Shimadzu, Japan) with gentisic acid (Aldrich, 99%) as the matrix. Thermogravimetric analysis (TGA) were carried out with DSC 822e (Piscataway, NJ) under
nitrogen with a scanning speed of 10 °C/min. X-Ray photoelectron spectroscopy (XPS) data were collected by an X-ray photoelectron spectrometer (ESCALAB 250) with a monochromatized Al Ka X-ray source (1486.71 eV). Elemental analysis was carried out using an organic elemental analyzer (Vario El III). Differential scanning calorimetry (DSC) was performed on DSC8500 (PerkinElmer, USA). Samples were measured in aluminium pans under nitrogen flow with a heating speed of 10 °C/min. An empty aluminium pan was used as the reference. FTIR spectra were obtained on a VERTEX-70/70v FT-IR spectrometer (Bruker Optics, Germany).

**Self-Assembly** For transmission electron microscopy (TEM) observations, about 5 µL of the specimen was placed on a TEM grid and the excess solution was wicked away with a piece of filter paper. The copper grids were dried with an infrared lamp and observed on a JEOL JEM-100 CXII (Japan) at an accelerating voltage of 120 kV. The high-resolution transmission electron microscopy (HRTEM) images were recorded on a HRTEM JEOL 2100 system operating at 200 kV. FE-SEM observations were carried out on a SU8010. Before measurements the samples were sputtered with Pt in a LEICA EM ACE 200 automatic sputter coater. For atomic force microscopy (AFM) observations, 5 µL of specimen solution was spin-coated on a silica wafer at a speed of 3000 r/s for 12s, and dried with an infrared lamp for 1-2 hours. The images were obtained by Tapping Mode operating with a Nanoscope IIIA at a scan frequency of 1.5 Hz and a resolution of 512×512 pixels. Dynamic light scattering (DLS) was performed on a Brookhaven BI-200SM instrument (USA). A 200 mW green laser (λ = 532 nm) with variable intensity was used, and measurements were carried out at room temperature with a scattering angle of 90°. The average radius and polydispersity index were calculated from the intensity autocorrelation data with the cumulants method. The intensity-intensity time correlation functions were analyzed by the CONTIN method. UV-vis measurements were performed using a HITACHIU-4100 spectrophotometer (Hitachi, Japan) with a scan rate of 600 nm/min.
Magnetic, Electrochemical and Photoresponsive Properties SQUID magnetometry were collected with a superconducting quantum interference device (MPMSXL, Quantum Design, USA) and a reciprocating sample option (RSO). The ESR spectrum was recorded on a Bruker E500 system. Cyclic voltammogram were obtained on a CHI 600E electrochemical analyzer. A Pt wire was used as the quasi-reference electrode and a Pt plate was used as the counter electrode. The ferrocene/ferrocenium (Fc/Fc+) redox couple was used as internal reference for the potential calibration. For the measurements of singlet oxygen (1O2) generation, stock solutions of 1 or 1b in water at the presence of 1% (v/v) DMSO were prepared and p-nitroso-N, N'-dimethylaniline (RNO) was used as an indicator. Solutions containing 1 or 1b were mixed with RNO (final concentration: 15 μmol·L⁻¹), imidazole (final concentration: 15 μmol·L⁻¹), and phosphate buffered saline (PBS, pH = 7.4, final concentration: 10 mmol·L⁻¹), which was then irradiated with green light (532 nm, 0.1 W/cm²). The time-dependent production of 1O2 was reflected by the decrease of RNO absorbance at 440nm. To determine the dark toxicity of 1, the same procedure was performed without irradiation.
2. Additional data

Scheme S1 Illustration of an alternative strategy to that given in the main text.

In this strategy, Tris was first attached to 1a via amidation (1a'), which was expected to directly couple with unmodified Dawson POM (1b'). However, this route was hindered due to the extremely low solubility of 1a' in almost all the common organic solvents.

Note that this strategy is commonly used to obtain POM derivatives. The failure in this case reveals the challenge of the covalent linking between C_{60} and POM due to the solubility mismatch, which could be one of the reasons for the very limit reports on C_{60}-POM hybrids.
Fig. S1 FTIR spectra of 1a, 1b, 1 and the physical mixture of 1a and 1b. Top: Full spectra from 4000 to 400 cm\(^{-1}\). Bottom: Magnified spectra in selected regions.
Fig. S2 XPS survey of 1b and 1. Top: Full spectra. Bottom: Fine spectra of C$_{1s}$.

From the results, the presence of signals from V$_{2p}$, W$_{4d}$ and W$_{4f}$ is evidenced in 1 and the peak intensity of the C$_{1s}$ is much stronger compared to 1b, which is unambiguously due to the attachment of C$_{60}$. Further deconvolution on C$_{1s}$ of 1 reveals the appearance of new signals from C=C (284.8 eV) and C=O (287.5 eV), both of which are absent in 1b.
Table S1 Results of elemental analysis for 1b and 1.
