General Information

$^1$H NMR experiments were recorded either on a Bruker AVANCE 300 MHz or 400 MHz instrument and calibrated to the residual solvent peak (e.g. CHCl$_3$ peak at 7.26 ppm). $^{13}$C NMR spectra were recorded at 75 MHz or 100 MHz and calibrated to the solvent peak (e.g. CDCl$_3$ at 77.23 ppm). The chemical shifts are reported in parts per million (ppm) relative to the corresponding protio-solvent signal. High-resolution mass spectra were obtained by EI on a Kratos Concept IIH or ESI on micromass Q-TOF. Infrared analysis was performed on an ABB Bomem Arid-Zone and the spectra were obtained as neat films on a sodium chloride window. Column chromatography was performed using silica gel, 40 microns flash silica. Thin layer chromatography was performed on silica gel (Silica Gel 60 F254) glass plates/aluminum back plates and the compounds were visualized by UV, 0.5% KMnO$_4$ in 0.1 M aqueous NaOH solution and/or 5% ninhydrin in EtOH. Unless otherwise noted, all reagents were used as is from commercial sources.

The commercially available HCl salts of α-aminonitriles 1c and 3n were used directly in the procedures below (with an extra equivalent of NaOH for deprotonation in situ) and unless detailed below known α-aminonitriles were synthesized according to literature procedures. Formaldehyde solution: a commercially available solution from Sigma-Aldrich was used (37 wt% in water).$^1$ Sodium hydroxide was used as a 5 M stock solution in water. The aldehydes and ketones used as catalysts were commercially available from Sigma-Aldrich.
Catalyst screening

*Procedure for the hydration of primary α-aminonitrile 1a*

2-Amino-4-methylthiobutyronitrile (0.075 g, 0.50 mmol) was taken up in D$_2$O (0.50 mL). NaOH (20 mL, 0.10 mmol) was added followed by the aldehyde (0.10 mmol). The mixture was allowed to stir for desired time at rt under argon. The reaction mixture was then diluted with DMSO-d$_6$ (0.50 mL). The reaction mixture was then evaporated under reduced pressure to remove majority of D$_2$O. A known amount of 1,3,5-trimethoxybenzene was added. The reaction was analyzed by $^1$H NMR and the yield was calculated using the 1,3,5-trimethoxybenzene as an internal standard.

*Procedure for the hydration of secondary α-aminonitrile 1b*

2-(N-Allylamino)-3-phenylpropionitrile (0.054 g, 0.39 mmol) was taken up in H$_2$O. NaOH (16 mL, 0.08 mmol) was added followed by the aldehyde (0.08 mmol). The mixture was allowed to stir for desired time at rt under argon. The reaction mixture was then diluted with EtOAc (5 mL) and H$_2$O (1 mL). The aqueous and organic layers were separated. The aqueous layer was extracted with EtOAc (4 x 5 mL). The combined organic layers were dried and concentrated. The crude was weighed and a known amount of 1,3,5-trimethoxybenzene (0.017 g, 0.10 mmol) was added. The resulting mixture was then dissolved in CDCl$_3$. The reaction was analyzed by $^1$H NMR and the yield was calculated using the 1,3,5-trimethoxybenzene as an internal standard. Yields and percentage conversions for different aldehydes are given in the table below (Table 1).

General procedure for the Synthesis of primary α-amino nitriles (Procedure A)

NaCN was taken up in H₂O (11.0 mL) and stirred for 5 min at rt. NH₄Cl (1.10 mmol) was then added. The reaction was stirred until almost all of the NH₄Cl (1.00 mmol) was dissolved. The aldehyde (1.00 mmol) dissolved in MeOH (11.0 mL) was then added to the reaction mixture. This was stirred vigorously for 12 h at rt. After completion, as indicated by TLC (petroleum ether/EtOAc, 85:15), the reaction mixture was diluted with EtOAc (20 mL). The aqueous and organic layers were separated and the aqueous layer was extracted with EtOAc (25 mL x 4). The organic layers were combined, dried over Na₂SO₄, filtered and concentrated under reduced pressure. The crude product was purified using flash column chromatography (petroleum ether/EtOAc/aq NH₄OH).

Figure S11. HPLC trace of (L)-N-t-(butoxycarbonyl)phenylalanine amide shows greater than 99% ee.
(L)-tert-Butyl(1-amino-1-oxo-3-phenylpropan-2-yl)(propyl)carbamate. (L)-3-Phenyl-2-(propylamino)propanenitrile (0.057 g, 0.30 mmol) was taken up in H₂O (0.3 M) followed by the addition of NaOH (5 M, 0.012 mL, 0.060 mmol) and acetone (0.022 mL, 0.30 mmol). The reaction was vigorously stirred at room temperature. The starting material was present both visually (large oil droplets) and by TLC after 1 h. The reaction was stirred for an additional 18 h with no change. The reaction was subsequently diluted with a saturated sodium bicarbonate solution (1 mL) and extracted with EtOAc (4 x 3 mL). The organic layers were combined, dried over Na₂SO₄, filtered and concentrated under reduced pressure for NMR analysis which showed pure starting material.

Reference

1. Over the course of this project, some variability was observed with aged bottles of formalin. For example bottles with a white precipitate (paraformaldehyde) led to variability in reaction results.
23. A control reaction performed in this solvent mixture also showed a slow background reaction (8%) in the absence of formaldehyde.
