Experimental section

Preparation of Polystyrene Spheres: Monodisperse polystyrene spheres with various sphere sizes were synthesized using a typical emulsion polymerization according to the literature. Typically, 100 mL of ultrapure water (18 MΩ/cm² @ 25 °C) and a certain amount of styrene were added into a three-necked, round-bottomed flask (250 mL). The mixture was stirred at 500 rpm, while being heated to 70 °C and purged with nitrogen gas with a flow rate of 100 mL/min. After the mixture was kept at 70 °C for 20 min, 0.1 g of K₂S₂O₈ was added and the reaction lasted for 12 or 24 h. The resulting polystyrene spheres were centrifuged at 8000 rpm to remove any large agglomerates in the bottom and then the remained polystyrene spheres were centrifuged at 12000 rpm to remove small spheres in the upper liquid. The obtained precipitates were redispersed in 100 mL of water to form a colloidal polystyrene spheres suspension until needed. In the present study, monodisperse polystyrene spheres with various sphere sizes were produced by changing the amount of styrene and the reaction time, keeping all other experimental conditions the same. The synthesis conditions of the as-prepared PS templates with various sphere diameters were shown in Table S1.
Table S1 The synthesis conditions of the as-prepared PS templates.

Notes:

The conduction band potential of semiconductor could be determined by the expression in the following according to the Xu et al.:

$$E_C = -\chi + 0.5 E_g$$

Where $\chi$ is the electronegativity of semiconductor, $E_g$ is the electronic band gap. The conduction band and valence band potential of In$_2$O$_3$ were -0.75 and 2.55 V vs RHE. The conduction band and valence band potential of CdS were -0.47 and 2.07 V vs RHE.
