S1 Syntheses

All chemicals and solvents were purchased from commercial sources and used as received without further purification.

S1.1 Conventional solvothermal synthesis of perfect UiO-66

3.78 g of ZrCl$_4$, 2.8 mL 35% HCl and 5.39 g of 1,4-benzenedicarboxylic acid (BDC) were dissolved in 98 mL of dimethylformamide (DMF). The synthesis mixture was stirred until the solution was completely transparent and then transferred to a Teflon liner and sealed in stainless steel autoclave where it was heated at 220 °C for 20 hours. After cooling down to room temperature, the solid was centrifuged and immersed in DMF at 100 °C for 150 minutes. The product was dried overnight at 24 °C using an extractor thimbles. The final product was dried in vacuum at 60 °C.

S1.2 Microwave-assisted d-UiO-66-aC syntheses (a = 05, 1, or 2, volume of additives used in the MOFs synthesis protocol; C = HCl or FA, HCl = concentrated hydrochloric acid; FA = formic acid)

Microwave syntheses of d-UiO-66-aCs were conducted using an Anton Paar Monowave 300 microwave oven. A 30 mL glass microwave vial was charged with 1 mmol ZrCl$_4$ (>99.9%, Sigma-Aldrich) and 1 mmol 1,4-benzenedicarboxylic acid (H$_2$bd, 98%, Sigma-Aldrich). Thereafter, concentrated hydrochloric acid (conc. HCl, 37%, Merck) or formic acid (reagent grade, ≥ 95%, Sigma-Aldrich) and N,N'-dimethylformamide (DMF, Ajax) were introduced. The mixture was heated with magnetic stirring to 180 °C within 2 min, and held at this temperature for 90 min before cooling to 55 °C within 2 min. The precipitates were vacuum filtered, and repeatedly washed with DMF and ethanol. The resulting powder was dried in vacuum. A summary of the reaction conditions is provided in Table S1.

Table S1 Synthesis conditions for the d-UiO-66-aCs using microwave heating.

$^a$d-UiO-66; $^b$H$_2$bd = 1,4-benzenedicarboxylic acid; $^c$for d-UiO-66-aFAs, addition of H$_2$O is crucial for pure UiO-66 phase, without which polymorphous MIL-140A phase appeared even at low synthesis temperature (140 °C); $^d$microwave heating, temperature ramp to 180 °C within 2 min.

S2 X-ray powder diffraction (XRPD)

XRPD measurements were performed on a PANalytical X’pert Pro diffractometer fitted with a solid-state PIXcel detector (45 kV, 40 mA, 1° divergence and anti-scatter slits, and 0.3 mm receiver and detector slits) using Cu-Kα ($λ = 1.5406$ Å) radiation. Profile fits were performed using the Le Bail extraction method in GSAS.$^3$
Figure S1 Full (5 – 40 °, left) and low-angle (5 – 10 °, right) XRPD spectra for d-UiO-66-aC (a = 0.5, 1, or 2, volume of additives used in the MOFs synthesis protocol; C = HCl or FA, HCl = concentrated hydrochloric acid; FA = formic acid), type of additives used in the MOFs synthesis protocol). The asterisks in the additional low-angle peak region for d-UiO-66-2FA represent the reo type defects.

In previous studies, UiO-66 (Hf or Zr) materials with ordered missing linker defects manifested characteristic symmetry forbidden reflections (indexing to the (100) and (110) peaks of the primitive cell) in the low angle region of their XRPD patterns (4-6°).\textsuperscript{2,3} In the present study, except for d-Uio-66-2FA, such weak and broad symmetry forbidden peaks were not observed, probably due to the high conc. HCl dosage used in the synthesis protocol, resulting in randomised rather than ordered defect-nano-regions (\textit{vide infra}).

**S3 Chemical formula determination for d-Uio-66-aC**

**S3.1 Thermogravimetric analysis**

TGA measurements were carried out on a DISCOVERY TGA Thermogravimetric Analyzer. Approximately 5 mg of sample was placed on a platinum pan which was heated under a flow of air at a rate of 5 °C.min\textsuperscript{-1} up to 700 °C.

![TGA graph showing weight loss relative to ZrO\textsubscript{2} for d-Uio-66-05HCl, d-Uio-66-1HCl, d-Uio-66-2HCl, d-Uio-66-4HCl, and d-Uio-66-6HCl. Dashed lines indicate the theoretical weight relative to ZrO\textsubscript{2} for UiO-66.](image)

Figure S4 Thermogravimetric analysis (TGA) showing the weight loss (relative to ZrO\textsubscript{2}) for d-Uio-66-05HCl, d-Uio-66-1HCl, d-Uio-66-2HCl, d-Uio-66-4HCl, and d-Uio-66-6HCl. Dashed lines indicate the theoretical weight (relative to ZrO\textsubscript{2}) for UiO-66.

**S3.2 Scanning electron microscopy-energy dispersive spectroscopy (SEM-EDS)**

Field-emission SEM (FE-SEM) images and EDS spectra were obtained using a Zeiss ULTRA plus microscope (working distance 9 mm; acceleration voltage 20 kV). Samples were prepared by dispersing the powdered solids in ethanol to produce a suspension that was deposited onto a carbon block and dried in air. EDS results are calculated as an average of at least 9 different areas of a samples.

![EDS spectra](image)

Figure S5 Examples of raw EDS spectra: UiO-66 (left) and d-Uio-66-05FA (right).
S3.3 Nuclear magnetic resonance (NMR)

$^1$H NMR spectra were recorded in deuterated solvents using a Bruker AVANCE200 NMR Spectrometer. The d-UiO-66-aCs (~20 mg) sample was digested in KOH/D$_2$O. The actual molecular ratio between formate and 1,4-benzenedicarboxylate was calculated by integrating the proton signals of the ligands in the $^1$H NMR spectra.

![Figure S7](image)

Figure S7 Examples of $^1$H NMR spectra of alkaline-digested (KOH/D$_2$O) d-UiO-66-aFA (a = 0.5, 1, and 2). Asterisk (*) indicates the proton signal of formate and hash mask (#) of 1,4-benzenedicarboxylate.
S3.4 Chemical formula determination for d-UiO-66-aCs

The presence of structural defects was evidenced by the aerobic decomposition of d-UiO-66-aC in TGA analysis. As shown in Figure 1b and S8, the TGA traces of all samples can be deconvoluted into three distinguished stages: solvent volatilization (~100 °C), compensating-agent elimination (250–350 °C), and framework decomposition (500–550 °C) (Figure 1b). Considering the chemical equation for perfect UiO-66(Zr), the molecular weight of [Zr₆O₄(OH)₄(bdc)₆]ₐ restrain product at 350 °C) is a factor of 2.2 higher than six ZrO₂ (only solid product at 700 °C). The concentration of the missing-linker defects can be addressed by comparison of the TGA plateau at 350 °C (solvent-free and dehydrated materials) and the end weight at 700 °C (ZrO₂).⁵,⁶ In addition, incorporation of formate, chloride and/or hydroxide anions to the [Zr₆O₄(OH)₄(bdc)]¹²⁺ cluster to compensate for linker deficiencies proved to be feasible both experimentally and theoretically.⁵,⁶ Although direct incorporation of Cl⁻ within the Zr-oxo cluster by replacing the -OH group, forming [Zr₆O₄Cl(OH)₃(bdc)]¹²⁺, is plausible at low synthesis temperatures, such a phenomenon is thermodynamically unfavorable in our case (T_synthesis = 180 °C).³ Thus, we just consider peripheral coordination of Cl⁻, HCOO⁻ and OH⁻ in the d-UiO-66 formula calculation.

Figure S8 Illustration of TGA patterns of UiO-66(Zr) shows three steps corresponding to, in turn, solvent volatilization (~100 °C), compensating-agent elimination (250–350 °C), and framework decomposition (500–550 °C).

The aerobic decomposition d-UiO-66-aCs can be expressed as the following equation:

\[
[Zr₆O₄(OH)₄(bdc)₆(HCOO)₆]_{a} \xrightarrow{350 \; ^{\circ}C} \frac{[Zr₆O₄(bdc)₆] + bHCOOH + cHCl + \frac{4 - b - c + d}{2}H₂O}{6}\]

where a, b, c, and d can be calculated via kₐ, k₇, and k₉ measured from TGA, ¹H NMR and EDS, respectively.

The atomic ratios between chloride and zirconium in d-UiO-66-aCs were measured by SEM-EDS analysis.

\[
k_c \equiv \frac{A_{Cl}}{A_{Zr}} = \frac{c}{6}
\]
A summary table for $k_a$, $k_b$ and $k_c$ is provided in Table S3. The actual values of $a$, $b$, $c$ and $d$ were calculated via solving the following equations using Excel (Microsoft Corporation).

\[
\begin{align*}
\frac{547.344 + 16 \times \frac{12 + b + c + d}{2}}{6 \times 123.218} + 164.113 \times a
\end{align*}
\]

\[
\begin{align*}
k_a &\equiv \frac{547.344 + 16 \times \frac{12 + b + c + d}{2}}{6 \times 123.218} + 164.113 \times a \\
k_b &\equiv b \\
k_c &\equiv \frac{a}{c} \\
6 \times 123.218 &\times 547.344 + 16 \times \frac{12 + b + c + d}{2} + 164.113 \times a
\end{align*}
\]

\[
a + b + c + d = 12
\]

S4 Adsorption analysis

S4.1 N₂ adsorption at 77 K and CO₂ adsorption under low-pressure (<1 bar)

N₂ sorption isotherms were recorded on a 3Flex Surface Characterisation Analyser (Micromeritics Instruments Inc.). Approximately 100 mg of the powdered solid was loaded into a glass analysis tube and
outgassed for 16 h under dynamic vacuum (~10⁻⁶ bar) at 160 °C. N₂ adsorption and desorption isotherms were measured at 77 K and the surface areas were calculated using the Brunauer–Emmett–Teller (BET)⁸ or Langmuir⁹ models. CO₂ adsorption and desorption isotherms were measured at 293, 303, and 313 K.

Figure S9 N₂ adsorption (filled circle) and desorption (open circle) isotherms, measured at 77 K.

The pore-size-distribution calculations were carried out using the MicroActive software DFT package (non-local density functional theory calculations, NLDFT, based on the N₂-Cylindrical Pores – Oxide Surface DFT model in the MicroActive software package, Micromeritics Instruments Inc.).

Calculation of the CO₂ heat of adsorption involves the generation of an interpolated curve by spline fitting of data points using MicroActive software (version 3.00, Micromeritics Instrument Corporation). This was used to fit data for CO₂ adsorption isotherms at 293, 303, and 313 K to the Clausius–Clapeyron equation, which was used to determine the isosteric enthalpy of adsorption at specific surface coverage.

**S4.2 CO$_2$ adsorption under high-pressure (< 35 bar)**

Prior to analysis, samples (~100 mg) were degassed under high vacuum for 24 hours at 160 °C. The high pressure CO$_2$ experiments were conducted at 298 K up to 35 bar using a high pressure volumetric analyser (Micromeritics HPV A-100).

S4.3 H₂O adsorption analysis

Water sorption isotherms were performed on a Hiden-Isochema Intelligent Gravimetric Analyser (IGA). Prior to adsorption, the sample was outgassed under vacuum (10⁻⁵ bar) at 160 °C overnight. Sample was cooled to analysis temperature (25 °C) and the dry mass recorded. The sample chamber was pressurized to a set pressure and allowed to equilibrate for 120 minutes before moving to the next pressure point.
Figure S20 Water adsorption (filled circle) and desorption (open circle) isotherms at 298 K for UiO-66, d-UiO-66-aHCl and d-UiO-66-aFA (a = 0.5, 1, or 2, volume of additives used in the synthesis protocol).

Figure S21 Derivative water adsorption isotherms at 298 K for UiO-66, d-UiO-66-aHCl and d-UiO-66-aFA (a = 0.5, 1, or 2, volume of additives used in the synthesis protocol).

S5 Density functional theory calculations

Static binding energies for CO₂ at zero Kelvin were calculated using the dispersion-corrected semi-empirical DFT-D2 method. All calculations were performed using Vienna *ab* initio simulation package (VASP) with a plane-wave energy cut-off of 500 eV and a Gamma-point mesh for sampling the Brillouin zone. The interactions between the core and valence electrons were described by the projector-augmented-wave (PAW) method, and the generalised gradient approximation (GGA) of Perdew-Burke-Ernzerhof (PBE) was used to parameterize the exchange-correlation functional. As reported earlier in many studies, the strongest site for CO₂ adsorption in UiO-66 is the hydroxyl group located inside the tetrahedral cages. Thus, in this work a cluster model was built consisting of Zr metal-oxide with 12 linkers which was cleaved from the unit cell of UiO-66. The effect of missing linkers on the interaction energy of CO₂ was modelled, where one BDC linker was removed and replaced with formate, chloride and hydroxide to compensate the charge. The defective and perfect cluster model was modelled using a cell size of 35 x 35 x 35 Å in order to avoid interactions between repeated images. The initial location of the CO₂ in the periodic cell was obtained from the classical simulated annealing technique. In the simulated annealing method, the temperature was lowered successively allowing the gas molecule to reach a desirable configuration based on different moves such as rotate, translate and re-position with preset probabilities of occurrence. This process of heating and cooling the system was repeated in several heating
cycles to find the local minima. Forty heating cycles were performed where the maximum temperature and the final temperature were $10^5$ K and 100 K, respectively. Static binding energies ($\Delta E$) at 0 K were calculated using the following expression;

$$\Delta E = E_{\text{cluster+gas}} - E_{\text{cluster}} - E_{\text{gas}}$$

where $E_i$ refers, respectively, to the total energies of the cluster + gas complex, the cluster, and an isolated gas molecule.

Figure S22 DFT - D2 optimised location and binding energy (B.E) of CO$_2$ for (a) perfect and defective cluster capped with (b) formate, (c) hydroxides and (d) chlorine group to compensate the charges.
