Methods

\textit{Materials Synthesis and Perovskite Film Fabrication:} The inorganic precursors of perovskite in this study, high purity PbI\textsubscript{2}, was purchased from the Alfa-Asar and was used as received. Non-purified methylammonium iodide (CH\textsubscript{3}NH\textsubscript{3}I, MAI) was synthesized with stabilized HI (Alfa Aesar, L10410) using the method described by Lee et al.\textsuperscript{1} MAI was also synthesized with non-stabilized HI (Alfa Aesar, 36484) following the same procedure as used for non-purified MAI. To purify the MAI, we first dissolved MAI in the isopropanol alcohol (IPA) and then heated the solution to 80 °C to obtain a supersaturated MAI solution. After cooling down the hot solution to room temperature, purified MAI crystal precipitated. Perovskite film based on both purified MAI and non-purified MAI were fabricated by the two-step inter-diffusion method.\textsuperscript{2}

MAH\textsubscript{2}PO\textsubscript{2} were synthesized by adding H\textsubscript{3}PO\textsubscript{2} aqueous solution into excess MA aqueous solution. After stirring for 90 min in ice bath, the solution was rotation-evaporated under 100 °C. The obtained MAH\textsubscript{2}PO\textsubscript{2} was transparent viscos liquid, which was kept in N\textsubscript{2} glove box. The intermediate phase of Pb(H\textsubscript{2}PO\textsubscript{2})\textsubscript{2} was synthesized by adding excess MAH\textsubscript{2}PO\textsubscript{2} into PbI\textsubscript{2} solution.
(dissolved in N,N-Dimethylformamide, DMF). The generated white precipitate was washed by diethyl ether and DMF respectively to remove unreacted PbI$_2$ or MAI before use. Perovskite films based on Pb(H$_2$PO$_2$)$_2$ were formed by drop-casting the mixed solution of Pb(H$_2$PO$_2$)$_2$ and MAI (dissolved in DMF) onto ITO substrate and annealing at 130 °C for 90 min.

Film Characterization: XRD measurements were performed with a Rigaku D/Max-B X-ray diffractometer with Bragg–Brentano para focusing geometry, a diffracted beam monochromatic, and a conventional cobalt target X-ray tube set to 40 kV and 30 mA. A Quanta 200 FEG environmental scanning electron microscope (ESEM) using a field-emission gun (FEG) electron source was used to scan the surface and cross-sectional film morphology. The films were first covered with a thin layer of gold, coated using a Cressington 108 Auto Sputter Coater, before the SEM measurement.

Device Fabrication and Characterization: PEDOT:PSS was spin-coated on the ITO substrate at 3000 rpm for 60 s. The perovskite films were deposited on the ITO/ PEDOT:PSS substrate by inter-diffusion process. The PCBM (dissolved in DCB, 2 wt%) was spin-coated on top of the perovskite layer at 6000 rpm for 35 s. Then the films were annealed at 100 °C for 60 min. The device was finished by thermal evaporation of C$_{60}$ (20 nm), BCP (8 nm), and Al (100 nm).

The photocurrent curves were measured under simulated AM 1.5G irradiation (100 mW cm$^{-2}$) using a xenon-lamp-based solar simulator (Oriel 67005, 150 W Solar Simulator). The scanning rate for the I–V curve was 0.13 V s$^{-1}$, excluding those marked specifically. For each measurement, the lamp was turned on and the testing started 30 min later. We did not intentionally do the light soaking process before the IV measurement, however, there might be around seconds of unintentional light soaking after we put the devices under light illumination before the IV measurement. A Schott visible-color, glass-filtered (KG5 color-filtered) Si diode (Hamamatsu S1133) was used to calibrate the light intensity before the photocurrent measurement.
