According to IUPAC and the previous reported work [1-4], the detection limits were determined based on the fluorescence titrations. Probe RosN$_3$ was employed at 10 µM. The emission intensity of probe RosN$_3$ was measured without NaHS by 11-times and the standard deviations of blank measurements were determined. To obtain the slope, the fluorescence intensity at 590 nm was plotted against the concentration of NaHS. The detection limit was calculated according to Eq. (1):

$$\text{Detection limit} = \frac{3\sigma}{k}$$  \hspace{1cm} \text{Eq. (1)}

where $\sigma$ is the standard deviation of the blank measurement, $k$ is the slope of fluorescence intensity vs. NaHS concentration.
