**TOF calculation.**

The number of active sites (n) is examined using CVs with 1 M KOH at a scan rate of 50 mV s⁻¹. When the number of voltammetric charges (Q) is obtained after deduction of the blank value, n (mol) can be calculated with the following equation:

\[ n = \frac{Q}{2F} \]

where F is Faraday constant (96485 C mol⁻¹). For the sample of CoMoS₄ with hydrothermal process (black), Q is 2.413×10⁻³ C (obtained from Fig. S17), n (mol) = \( \frac{2.413 \times 10^{-3}}{2 \times 96485} \) mol = 1.25×10⁻⁸ mol. And for the sample of direct precipitation (red), Q is 1.299×10⁻³ C, n (mol) = \( \frac{1.299 \times 10^{-3}}{2 \times 96485} \) mol = 6.73×10⁻⁹ mol.
Fig. S17 Cyclic voltammograms of blank CC (blue), amorphous CoMoS₄ with hydrothermal process (black) and direct precipitation (red) recorded in 1.0 M KOH; scan rate: 50 mV s⁻¹

When the number of active sites is obtained, the per-site turnover frequencies (in s⁻¹) were calculated with the following equation:

\[
\text{TOF} = \frac{I}{2Fn}
\]

I —Current (in A) during the linear sweep measurement.
F —Faraday constant (96485 C mol⁻¹).
n —Number of active sites (in mol).

The factor \(1/2\) in the equation represents that two electrons are required to form one hydrogen molecule from two protons (\(2\text{H}^+ + 2e^- = \text{H}_2\)).
**Fig. S18** Calculated turnover frequencies for amorphous CoMoS₄ with hydrothermal process (black) and direct precipitation (red).

**Current calibration.**
The capacitances of the double layer at the solid–liquid interface of electrodes with different mass loading were measured by cyclic voltammograms (CVs) collected in the region of 0.0–0.10 V at scan rate of 5 mV/s, where the current response should be only due to the charging of the double layer (Fig. S19). All the LSV curves were calibrated with capacitive current reduction.

![Current Calibration Graph](image)

**Fig. S19** CVs for CoMoS₄/CC electrode with CoMoS₄/β-Co(OH)₂ composites with different mass loading in 1.0 M KOH solution.

![SEM Images](image)

**Fig. S20** SEM images of the CoMoS₄/CC electrode with CoMoS₄/β-Co(OH)₂ composites after HER cycles (a) and after OER cycles (b), respectively.
The samples after cycles were obtained by loading amorphous CoMoS$_4$ onto Ni foam (Ni foam was applied as substrate here because the diffraction peaks of carbon cloth is so strong that the rest peaks would not be easily showed), followed by running 2000 CV cycles and washing with absolute ethanol, then the active material was transferred into ethanol under ultrasound for further characterization.

**Loss of active material during long time electrolysis.**

An electrolyzer with carbon cloth (1×1 cm$^2$) loading 1.0 mg cm$^{-2}$ amorphous CoMoS$_4$ as both anode and cathode, 1.0 M KOH as electrolyte, worked at current density of 10 mA cm$^{-2}$ for 12 hours electrolysis, and Co, Mo, S can be detected in the electrolyte after digesting by HNO$_3$. The results showed ~7% total mass loss for the electrolyzer.

**Table S2** Elemental content detected in the electrolyte after 12 hours electrolysis.
