S1. Microfluidic chip design for smaller double emulsion droplets generation

![Microfluidic chip design](image)

**Figure S1.** A microfluidic chip that is fabricated to generate smaller double emulsion droplets.
S2. Solvent Extraction of the PDMS

Solvent extraction of the cured PDMS sections was performed using Soxhlet extraction against 2-propanol (Figure S1). The PDMS sections were placed in a Soxhlet thimble, and the solvent raised to its boiling point. Condensation of the vapour causes the solvent to fill the section containing the solid material, washing the PDMS and extracting the uncured oligomers. Once this section is full, the solvent empties into the still pot via a siphon action and the cycle continues. This extraction process was run for 4 days.

Figure S2. Set-up for PDMS extraction: hot plate, still pot, Soxhlet thimble and condenser. PDMS was put in Soxhlet thimble and 2-propanol (IPA) was used as the solvent.
S3. **Statistical Analysis of the Patterning and Coating Results**

In order to show the reliability of our chip fabrication method, 12 chips were patterned with epoxy and were then plasma-treated for 2.5 mins. Drops of 0.24 wt% Rhodamine 6G solution were then placed in zones 1 and 3. The region filled with red color is hydrophilic, while the white region is hydrophobic. The results are illustrated in Fig. S3.

S4. Statistical Analysis of Double Emulsion Formation

The reproducibility of double emulsion generation in the fabricated chips was also investigated. Five chips with the larger channel dimensions (channel depth 110 µm, and widths 85 µm, 150 µm and 250 µm for the first, second and third channel zones) and five with the smaller dimensions (channel depth 23 µm, and widths 40 µm, 60 µm and 110 µm for the first, second and third channel zones) were used to generate double emulsion droplets under flow rates of 40 µl h\(^{-1}\) – 50 µl h\(^{-1}\) – 500 µl h\(^{-1}\) and 30 µl h\(^{-1}\) – 50 µl h\(^{-1}\) – 700 µl h\(^{-1}\) (inner water – oil phase – outer water). The droplets were collected and the size distributions of 1200 droplets are shown below. “Relative frequency” represents the relative number of double emulsion droplets and single phase droplets generated by the prepared devices, as well as the size distribution of cores and shells of double emulsion droplets.

![Histograms of 1200 droplets generated by (a) 5 chips with larger channel sizes and (b) 5 chips that generate small double emulsion droplets. “Core” and “shell” represent the core and shell of the double emulsion droplets, and “single” represents single phase droplets (ie double emulsion droplets failed to form). The flow rates were held at 40 µl h\(^{-1}\) – 50 µl h\(^{-1}\) – 500 µl h\(^{-1}\) and 30 µl h\(^{-1}\) – 50 µl h\(^{-1}\) – 700 µl h\(^{-1}\) (inner water – oil phase – outer water) for (a) and (b) respectively.](image)
