Experimental Section:

Materials and Methods:

1-pyrenemethylamine hydrochloride, thymine, bromoacetyl chloride and uric acid were purchased from Sigma-Aldrich Pvt.Ltd. (India). Unless otherwise mentioned, materials were obtained from commercial suppliers and were used without further purification. Solvents were dried according to standard procedures. Elix Millipore water was used throughout all experiments. \(^1\)H and \(^{13}\)C NMR spectra were recorded on a Bruker 400 MHz instrument. For NMR spectra, DMSO-d\(_6\) and for NMR titration D\(_2\)O was used as solvent using TMS as an internal standard. Chemical shifts are expressed in \(\delta\) ppm units and \(^1\)H–\(^1\)H and \(^1\)H–C coupling constants in Hz. The mass spectrum (HRMS) was carried out using a micromass Q-TOF Micro™ instrument by using Methanol as a solvent. Fluorescence spectra were recorded on a Perkin Elmer Model LS 55 spectrophotometer. UV spectra were recorded on a SHIMADZU UV-3101PC spectrophotometer. FTIR spectra was recorded as KBr pellets using a SHIMADZU FTIR-8400S spectrophotometer. Elemental analysis of the compounds was carried out on Perkin-Elmer 2400 series CHNS/O Analyzer. The following abbreviations are used to describe spin multiplicities in \(^1\)H NMR spectra: s = singlet; d = doublet; t = triplet; m = multiplet.

Synthetic Procedure:

2-Bromo-N-(pyren-1-ylmethyl)acetamide (1): 1-pyrenemethylamine hydrochloride (0.804 g, 3 mmol) mixed with potassium carbonate (1.68 g, 12 mmol) is suspended into a mixture of ethyl acetate (120 mL) and water(120 mL). Then, bromoacetyl chloride (7.07 g, 4.5 mmol) in ethyl acetate (10 mL) is added dropwise into the solution. After 2 h stirring at room temperature, the organic layer is isolated and dried by MgSO4. The ethyl acetate solvent is removed by rotary evaporation to give the crude product that is purified by column chromatography (silica, 220–400 mesh, hexane/ EtOAc = 1:3 v/v). The product is isolated as a white powder 1 (0.76 g, 72%). \(^1\)H-NMR (DMSO-d\(_6\), 400 MHz): \(\delta\) (ppm)  4.41 (s, 2H), 5.05 (d, \(J = 8\) Hz, 2H), 8.07–8.33 (m, 9H), 8.92 (t, \(J = 8\) Hz, 1H); \(^{13}\)C-NMR (DMSO-d\(_6\), 400 MHz): \(\delta\) (ppm) 30.1, 123.7, 124.3, 124.5, 125.2,125.7, 125.8, 126.8, 127.3, 127.6, 127.8, 128.3, 128.6, 130.7, 131.2, 132.7, 167.0. ESI/MS: m/z calcd for C\(_{19}\)H\(_{14}\)BrNO: 352.02, found [M+H]\(^+\): 353.04. Anal.Calcd for C\(_{19}\)H\(_{14}\)BrNO: C, 64.79; H, 4.01; N, 3.89. Found: C, 64.88; H, 4.07; N, 3.81.

PTA: To a solution of anhydrous K\(_2\)CO\(_3\) (2.5g, 18 mmol) in dry DMF was added thymine (0.2 g, 1.50 mmol). The mixture was stirred for 0.5 h. Then compound 1 (0.85 g, 2.5 mmol) was added to the solution and stirred for 48 h. Then, the reaction mixture was poured into water. The
solution was extracted with EtOAc (3×50 mL), and the combined organic layer was washed with 5% aqueous HCl (50 mL), 10% aqueous Na₂CO₃ (50 mL) and finally with water and then was dried over by anhydrous MgSO₄. After removing the solvents, the residue was chromatographed on silica gel with Ethyl acetate/methanol=8:1 v/v as eluent to give 0.05g (23%) of compound 1 as brown solid. ¹H NMR (DMSO-d₆, 400 MHz): δ (ppm) 1.78 (s, 3H), 4.41 (s, 2H), 5.05 (d, J = 8 Hz, 2H), 7.51 (s, 1H), 8.07-8.38 (m, 10H), 8.92 (t, J = 8 Hz, 1H). ¹³C-NMR (DMSO-d₆, 400 MHz): δ(ppm) 12.87, 41.45, 50.50, 63.75, 108.93, 124.08, 124.84, 124.94, 125.65, 126.12, 126.22, 127.21, 127.56, 128.01, 128.32, 128.55, 131.09, 131.25, 131.73, 133.35, 143.25, 152.05, 165.63, 167.94. FTIR (cm⁻¹) : 3160.98 (N-H str.), 2370.35 (C=C), 1695.31 (C=O str.), 2910.68 (sp³-CH₃). HRMS (TOF MS): (m/z, %): 420.2314 [(M+Na⁺), 100 %]; Calculated for C₂₄H₁₉N₃O₃: 397.4271. Anal. Calcd for C₂₄H₁₉N₃O₃: C, 72.55; H, 4.79; N, 10.57; O, 12.09; Found: C, 72.58; H, 4.77; N, 10.59; O, 12.06.

\textbf{1H NMR titration spectrum of PTA with UA:}

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{spectrum.png}
\caption{Partial \textsuperscript{1}H NMR titration [400MHz] of PTA in D\textsubscript{2}O at 25\textdegree{}C and the corresponding changes after the gradual addition of different equiv. of UA in D\textsubscript{2}O from a) only PTA, b) PTA+ 1 equiv. of UA, c) PTA+1.5 equiv. of UA, d) PTA+ 2ev. of PTA; [inset] UA.}
\end{figure}

\textbf{8. Evaluation of the Association constants for the formation of PTA-UA:}

\textbf{By UV-Vis Method:}
The substrate binding interaction was calculated according to the Benesi-Hildebrand equation.

\[ \frac{A_0}{A - A_0} = \left( \frac{\varepsilon_0}{\varepsilon_0 - \varepsilon} \right)^2 \left( \frac{1}{K_B [\text{Substrate}]} + 1 \right) \]

\[ \text{.........(i)} \]

Here \( A_0 \) is the absorbance of receptor in the absence of guest, \( A \) is the absorbance recorded in the presence of added guest, \( \varepsilon_0 \) and \( \varepsilon \) are the corresponding molar absorption co-efficient and \( K_B \) represents the substrate binding interaction with guest.
Binding constant calculation graph (Absorption method):

**Figure S8.** Linear regression analysis (1/[G] vs 1/ΔI) for the calculation of association constant values by UV-titration method.

The association const.(Kₐ) of PTA for sensing UA was determined from the equation: Kₐ = intercept/slope. From the linear fit graph we get intercept = 3.66842, slope = 1.60096 × 10⁻⁴.

Thus we get, Kₐ = 3.66842/(1.60096×10⁻⁴) = 2.30×10⁴.

**Figure S9.** Changes of relative absorption intensity (A/A₀) of PTA (0.1 μM) as a function of [UA]/[PTA].
**By Fluorescence Method:**

Binding constant of the chemosensor **PTA** also be calculated through emission method by using the following equation.

\[
\frac{1}{(I - I_0)} = \frac{1}{K(I_{\text{max}} - I_0)}[G] + \frac{1}{(I_{\text{max}} - I_0)} \quad \text{(ii)}
\]

where \(I_0\), \(I_{\text{max}}\), and \(I\) represent the emission intensity of free **PTA**, the maximum emission intensity observed in the presence of added **UA** at 377 nm \((\lambda_{\text{ex}} = 315 \text{ nm})\), \([G]\) is the concentration of the guest **UA** and the emission intensity at a certain concentration of the **UA**, respectively.

8B. **Binding constant calculation graph (Fluorescence method):**

![Graph showing linear regression analysis](image)

**Figure S10.** Linear regression analysis \((1/[G] \text{ vs } 1/\Delta I)\) for the calculation of association constant values by Fluorescence titration method.

The association const.\((K_a)\) of **PTA** for sensing uric acid was determined from equation:

\[K_a = \text{intercept/slope}.\]

From the linear fit graph we get intercept= -0.00634, slope = \(2.04236 \times 10^{-7}\). Thus we get, \(K_a = 0.00634/2.04236 = 3.10 \times 10^4\).
Figure S11. Fluorescence intensity changes of PTA (0.1 μM) upon addition of various concentration of UA.

Calculation of limit of detection (LOD):

The detection limit of the receptors for UA was calculated on the basis of fluorescence titration. To determine the standard deviation for the fluorescence intensity, the emission intensity of four individual receptors without UA was measured by 10 times and the standard deviation of blank measurements was calculated. The limit of detection (LOD) of PTA for sensing UA was determined from the following equation:

\[
\text{LOD} = K \times \frac{SD}{S}
\]

Where \( K = 2 \) or 3 (we take 2 in this case); SD is the standard deviation of the blank receptor solution; S is the slope of the calibration curve.

Figure S12. Linear fit curve of PTA at 377 nm with respect to UA concentration.
For PTA with UA:
From the linear fit graph we get slope = $6.11083 \times 10^6$, and SD value is 1.58283
Thus using the above formula we get the Limit of Detection = $5.1804 \times 10^{-7}$ M. i.e 0.518 µM.
Therefore PTA can detect UA up to this very lower concentration by fluorescence techniques.

**Job’s plot for determining the stoichiometry of PTA and UA by fluorescence method:**

![Job's plot](image)

**Figure S13.** Job’s plot of PTA with UA in water, 10 mM HEPES buffer, pH 7.4, ([PTA] = [UA] = $1 \times 10^{-4}$ M) by fluorescence method, which indicates 1:2 stoichiometry.

**pH titration study of PTA:**

![pH titration](image)

**Figure S14.** Change in fluorescence intensity of free chemosensor PTA (black) and in presence of 2 equiv. of UA in water ($1 \times 10^{-4}$M) (red) at $\lambda_{ex}$ 315 nm (10 mM HEPES buffer, pH 7.4) with different pH conditions.
UV-vis spectral studies:

A stock solution of probe PTA \((1 \times 10^{-5} \text{ M})\) was prepared in water. An UA solution of concentration \(1 \times 10^{-4} \text{ M}\) was prepared in Millipore water. All experiments were carried out in water (10 mM HEPES buffer, pH 7.4). During titration, each time a \(1 \times 10^{-5} \text{ M}\) solution of PTA was filled in a quartz optical cell of 1 cm optical path length and UA stock solution was added into the quartz optical cell gradually by using a micropipette. Spectral data were recorded at 1 min after the addition of UA.

Fluorescence spectral studies:

**Computational details:** Geometries have been optimized using the B3LYP/Def2SVP level of theory in presence of solvent water. Solvent effects were incorporated using COSMO solvent model\(^1\) implemented in ORCA.\(^2\) The geometries are verified as proper minima by frequency calculations. Time-dependent density functional theory calculation has also been performed at the same level of theory. All the calculations have been carried out using ORCA software suite.\(^2\)

**Live Cell Imaging:**

**Cell line and cell culture**

Vero cell (Vero 76, ATCC No CRL-1587) lines were prepared from continuous culture in Dulbecco’s modified Eagle’s medium (DMEM, Sigma Chemical Co., St. Louis, MO) supplemented with 10% fetal bovine serum (Invitrogen), penicillin (100 μg/mL), and streptomycin (100 μg/mL). The Vero 76 were obtained from the American Type Culture Collection (Rockville, MD) and maintained in DMEM containing 10% (v/v) fetal bovine serum and antibiotics in a CO\(_2\) incubator. Cells were initially propagated in 75 cm\(^2\) polystyrene, filter-capped tissue culture flask in an atmosphere of 5% CO\(_2\) and 95% air at 37°C in CO\(_2\) incubator. When the cells reached the logarithmic phase, the cell density was adjusted to 1.0 x 10\(^5\) per/well in culture media. The cells were then used to inoculate in a glass bottom dish, with 1.0 mL (1.0 x 10\(^4\) cells) of cell suspension in each dish. After cell adhesion, culture medium was removed. The cell layer was rinsed twice with phosphate buffered saline (PBS), and then treated according to the experimental need.
Cell imaging study

For confocal imaging studies Vero cells, $1 \times 10^4$ cells in 1000 $\mu$L of medium, were seeded on sterile 35 mm $\mu$-Dish, glass bottom culture dish (ibidi GmbH, Germany), and incubated at 37°C in a CO$_2$ incubator for 10 hrs. Then cells were washed with 500 $\mu$L DMEM followed by incubation with $1.0 \times 10^{-4}$ M UA dissolved in 500 $\mu$L DMEM at 37°C for 1 hr in a CO$_2$ incubator and observed under an Olympus IX81 microscope equipped with a FV1000 confocal system using 1003 oil immersion Plan Apo (N.A. 1.45) objectives. Images obtained through section scanning were analyzed by Olympus Fluoview (version 3.1a; Tokyo, Japan) with excitation at 285nm and 312 nm monochromatic laser beam, and emission spectra were integrated at over the range 300-450 nm (single channel). The cells were again washed thrice with phosphate buffered saline PBS (pH 7.4) to remove any free UA and incubated in PBS containing probes PTA to a final concentrations of $10^{-5}$ M, incubated for 10 min followed by washing with PBS three times to remove excess probe outside the cells and images were captured. According to the need of the experiment we follow similar procedures to label the cell nuclei by treatment with DAPI (1 $\mu$g/mL) followed by three times wash with PBS and subsequently image was captured with excitation wavelength of laser was 350 nm, and emission was 470 nm. For all images, the confocal microscope settings, such as transmission density, and scan speed, were held constant to compare the relative intensity of intracellular fluorescence.

Cytotoxicity Assay

The cytotoxic effects of probe PTA and PTA-UA complex were determined by an MTT [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide] assay following the manufacturer’s instruction (MTT 2003, Sigma-Aldrich, MO). Vero cells were cultured into 96-well plates ($10^4$ cells per well) for 24 h. After overnight incubation, the medium was removed and various concentrations of PTA and PTA-UA complex (0, 5, 25, 50, 75 and 100 $\mu$M) made in DMEM were added to the cells and incubated for 24 h. Control experiments were set with DMSO, cells without any treatment and cell-free medium were also included in the study. Following incubation, the growth medium was removed and fresh DMEM containing MTT solution was added. The plate was incubated for 3-4 h at 37°C. Subsequently, the supernatant was removed, the insoluble colored formazan product was solubilized in DMSO, and its absorbance was measured in a microplate reader (Perkin-Elmer) at 570 nm. The assay was performed in triplicate for each concentration of PTA and PTA-UA. The OD value of wells containing only DMEM medium was subtracted from all readings to get rid of the background influence. The cell viability was calculated by the following formula: (mean OD in treated wells / mean OD in control wells) X 100.
Figure S120: MTT assay to determine the cytotoxic effect of PTA and PTA-UA complex on Vero 76 cells.
