Supplementary Information: Identification of a major intermediate along the self-assembly pathway of an icosahedral viral capsid by using an analytical model of spherical patch

Didier Law-Hine, Mehdi Zeghal, Stéphane Bressanelli, Doru Constantin and Guillaume Tresset

Experiment reproducibility

The mixing achieved with the stopped-flow device was found to be of high quality and the TR-SAXS patterns were very reproducible (Fig. 1).

Fig. 1 Reproducibility of the TR-SAXS experiments. (Left) The two sets of kinetic data collected at a protein concentration of 1.49 mg/mL superimpose very well at low q-values. (Right) Same patterns shifted for clarity. One of the experiments ends up at 305 s.

Dimers

Figure 2 demonstrates that the objects at the beginning of the self-assembly process were dimers. The first pattern of the kinetics was compared to the form factor of dimers measured separately in static experiments and to the form factor of dimers calculated from their crystal structure. The three patterns are in excellent agreement.

Model of empty capsid

Figure 3 shows a vesicle model used to describe the form factor of empty capsids. The volume of the capsid could be then calculated as well as the volume of the dimer. Since the capsid volume is 90 times higher than the dimer volume, the latter was found to be $V_{dimer}=79 \times 100 \, \text{Å}^3$.

Construction of the analytical model for the intermediate

Stereographic projection

Using the notations of Fig. 1 in the article, simple geometrical considerations lead to

\[ \theta_c(\phi) = 2 \arctan \left( \frac{\rho(\phi)}{2R} \right) \]

where \( \rho(\phi) \) denotes the radial distance in the 2D plane of the ellipse. For an ellipse of semi-axes \( a \) and \( b \) \((b > a)\), we have

\[
\begin{align*}
&\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \\
&x = \rho(\phi) \cos \phi, \ y = \rho(\phi) \sin \phi \\
&\rho(\phi) = \frac{ab}{\sqrt{b^2 \cos^2 \phi + a^2 \sin^2 \phi}}
\end{align*}
\]

Scattering intensity and form factor

Constantin showed that the scattering intensity can be expressed as

\[
I(q) = 4\pi \sum_{l=0}^{\infty} \sum_{m=-l}^{l} |c_{lm}|^2 |b_l(q)|^2
\]

The basis functions \( b_l(q) \)

\[
b_l(q) = \int_0^\infty a(r) r^2 j_l(qr)dr
\]

\[
= \frac{1}{q^2} \int_0^\infty a(z) j_l(z^2)dz, \ (z = qr)
\]

\[
= \frac{1}{q^2} \int_{z_{\text{max}}}^{z_{\text{min}}} j_l(z^2)dz, \ (z_{\text{max}} = qR_{\text{max}}, z_{\text{min}} = qR_{\text{min}})
\]

The last integral admits an analytical expression yielding

\[
b_l(q) = \frac{1}{q^2} \left[ \frac{\sqrt{\pi}}{2^{l+2}z} C_l^l \left( \frac{l+1}{2} \right) I_1 \left( \frac{l+3}{2} \frac{2l+3}{2} \frac{l+5}{2} \frac{z^2}{4} \right) \right]_{\text{max}}^\text{min}
\]

where \( \Gamma \) is the Gamma function and \( I_1 \) is a regularized hypergeometric function.

Coefficients \( c_{lm} \)

The coefficients \( c_{lm} \) result from the projection of the ellipse of semi-axis \( a,b \) on the sphere of radius \( R \) and contain the information on the shape of the intermediate. They are defined in terms of the scalar product

\[
c_{lm} = \langle Y_{lm}(\Omega), F(\Omega) \rangle
\]

\[
= \int_{\Omega} Y_{lm}^*(\Omega') F(\Omega')d\Omega'
\]

\( F \) is the characteristic function of the object of interest defined by:

\[
F(\Omega) = F(\theta, \phi) = \begin{cases} 
1, & \text{if } \theta \in [0, \theta_{c}(\phi)] \\ 
0, & \text{otherwise}
\end{cases}
\]

Thus,

\[
c_{lm} = \int_{\phi=0}^{2\pi} \int_{\theta=0}^{\theta_{c}(\phi)} \sqrt{\frac{2l+1}{4\pi}} \sqrt{\frac{(l-m)}{(l+m)}} P_l^m(\cos \theta) e^{-im\phi} \sin \theta d\theta d\phi
\]

Since the basis functions do not depend on \( m \), we can introduce the coefficients \( c_l \) defined by

\[
c_l = \sum_{m=-l}^{l} |c_{lm}|^2
\]

Calculation of \( c_{l(-m)} \): From Eq. 3 and the properties of the associated Legendre polynomials,

\[
c_{l(-m)} = (-1)^m c_{lm}^*
\]

Hence,
\[ c_l = \sum_{m=0}^{l} |c_{lm}|^2 + \sum_{m=-l}^{0} |(-1)^m c_{lm}^*|^2 - |c_{l0}|^2 \]

\[ = 2 \sum_{m=0}^{l} |c_{lm}|^2 - |c_{l0}|^2 \]

Odd values of \( m \): Still from Eq. 3, due to the term \( e^{-im\phi} \) and because the object is symmetrical, every odd value of the index \( m \) leads to \( c_{lm} = 0 \).

These two points reduce considerably the computation of the coefficients \( c_{lm} \) and thus \( c_l \) (by a factor of 4).

**Form factor**

The normalized form factor is defined as:

\[ P(q) = \frac{\sum_{l} c_l |b_l(q)|^2}{\sum_{l} c_l |b_l(0)|^2} \]

From Eq. 1 and using \( I(q) = V_{\text{int}}^2 P(q) \), where \( V_{\text{int}} \) is the volume of the intermediate, we have

\[ V_{\text{int}}^2 = 4\pi \sum_{l} c_l |b_l(0)|^2 \]

and \( P(q) \) can be expressed by

\[ P(q) = \frac{4\pi}{V_{\text{int}}^2} \sum_{l} c_l |b_l(q)|^2 \]

**Global fitting**

The global fitting procedure used in this study was carried out as follows:

1. The stoichiometric coefficients to be tested, i.e., \( \alpha, \beta \) and \( \gamma \), were first set according to the kinetic model and the fit parameters to be calculated were \( \{ \xi_i \} = \{ k_i^- , k_i^+ , \mu_i , \nu \} \).

2. Several initial sets of parameters \( \{ \xi_i^0 \} \) were randomly picked (uniform distribution) in their chosen range of values defined with lower and upper bounds \( \{ \xi_{\text{min}}^i , \xi_{\text{max}}^i \} \).

3. A loop over all the parameters \( \{ \xi_i \} \) was implemented using Sequential Quadratic Programming (SQP) and Interior-Point (IP) algorithms. The matrix of concentrations \( c_{\text{cat}}(\{ k_i^- , k_i^+ , \mu_i \}) \) was calculated by solving the coupled differential equations. The matrix \( P^* \) was computed as a function of \( v \). The residual \( \chi^2 \) that made the relationship \( I \approx I_{\text{cat}}^\text{optimal} \) was then stored as well as the corresponding R-factor.

4. Steps 2 and 3 were then repeated for other sets of stoichiometric coefficients.

**Nucleation-elongation and three-state cooperative models**
