Calculation details:

Computations of free-energy for the hydrogen evolution reaction (HER) were carried out using density-functional theory as implemented in VASP 5.2. The PW91 GGA functional and the projector augmented wave (PAW) technique were used to treat the exchange-correlation energy and the ion-electron interaction. For geometric optimization, both lattice constants and atomic positions were relaxed until the forces on atoms were less than 0.02 eV Å$^{-1}$ and the total energy change was less than $1.0 \times 10^{-5}$ eV. The Brillouin zone was sampled using k-points with 5*5*1 grid in the Monkhorst-Pack scheme for geometry optimization.

During the optimization, the bottom layer of model was fixed and the cut-off energy for plane waves is 400 eV. The hydrogen binding energy $\Delta E_H$ was calculated by $\Delta E_H = E_{H@slab} - E_{slab} - 1/2$.
The free energies at 298.15 K were obtained using $\Delta G = \Delta E_{\text{H}} + \Delta ZPE - T \Delta S$ according to previous work where $\Delta ZPE - T \Delta S = 0.24 \text{eV}$ for model of metal and metal oxide surface. $\Delta E_{\text{H}}$ is the hydrogen binding energy, $\Delta ZPE$, $\Delta S$ and $U$ are the zero point energy changes, entropy changes, respectively.

Results and Discussion

The formation mechanism of MoO$_x$/MoC$_x$ by carburization of polyoxometalate-based metal-organic frameworks (POMOFs, NENU-5) has been explained by previous studies. Actually, the decomposition of phosphomolybdic acid (PMo$_{12}$) occurs at the temperature below 500°C, meanwhile, MoO$_3$ is formed. As the temperature increase, oxygen molecules were removed by combining with the pyrolysis carbon to form carbon dioxide (CO$_2$). At the same time, Mo (VI) turns into Mo (IV) and MoO$_3$ is reduced to MoO$_2$ which is relatively stable at the high temperature. However, with the carbonizing temperature as well as time increased, Mo$_2$C could be formed. Similarly, in this work, during the carburization process, the organic ligands (btc$^3$- ) of precursor played two important roles: a) combining with the oxygen in the mixtures to form CO$_2$ gas and b) acting as carbon source to form MoO$_x$ and MoC$_x$. As illustrated in Figure S4, MoO$_2$ could be obtained at 700 °C for 3 h. While increasing the carbonizing time to 4h, the main diffraction peaks can be indexed to MoO$_2$ and MoC (JCPDS no. 89-4305). Besides, we can only get MoC if the carbonizing time increased to 5h (Figure S5). Therefore, the carburizing time is an important factor.
that would affect the formation of final product.
