SI.1 Experimental Details

All reactions were carried out under a dry, oxygen free nitrogen atmosphere using standard Schlenk and glovebox techniques in dry degassed solvents unless otherwise specified. All solvents were collected freshly distilled over calcium hydride (acetonitrile) or sodium wire (heptane). Deuterated NMR solvents were dried over activated molecular sieves and degassed with dry nitrogen (CD$_3$CN) or used as purchased in ampules (C$_6$D$_6$). 1,2-difluorobenzene, purchased from Fluorochem, was stirred over alumina followed by vacuum transfer from CaH$_2$ and finally stored over activated molecular sieves. Ammonium tetraphenylborate was purchased from Sigma Aldrich and dried overnight under vacuum at 100 °C. HBpin was purchased from Sigma Aldrich, distilled, and stored under dry nitrogen in a Young’s flask. All pyridines were stirred over CaH$_2$, distilled or sublimed, and stored under dry atmosphere.

NMR spectra were recorded at 298.0 K on a Bruker 400 MHz AvIII HD Smart Probe spectrometer ($^1$H at 400 MHz, $^{11}$B 128 MHz, $^{13}$C 101 MHz) unless otherwise specified. Chemical shifts (δ, ppm) are given relative to residual solvent signals for $^1$H and $^{13}$C, to external BF$_3$·Et$_2$O for $^{11}$B, with coupling constants (J) reported in Hz. The multiplicities of NMR resonances are denoted by the abbreviations s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), and combinations thereof for highly coupled systems.

High-resolution mass spectra (HRMS) were collected using a Waters Xevo G2-S QTOF mass spectrometer in positive mode using CH$_3$CN.

Single crystal X-ray diffraction was carried out at 180(2) K on a Bruker D8-Quest PHOTON-100 diffractometer equipped with an Incoatec IμS Cu microsource (λ = 1.5418 Å). Structures were solved using SHELXT$^1$ and refined using full-matrix least squares on $F^2$ using SHELXL-2014.$^2$

SI.2 Synthetic Procedures

**General procedure for NMR-scale reactions:**

In a glove box, ammonium tetraphenylborate (5mg, 2.5 mol%, 0.0148 mmol) was dissolved/suspended in dry solvent (0.5 mL CD$_3$CN, C$_6$D$_6$, or heptane). This solution was transferred to a J. Young NMR tube. For reactions conducted in heptane, a DMSO-$d_6$ capillary
was included. The desired pyridine (0.593 mmol) was then added, followed by 1.5 equivalents HBpin (0.13 mL, 0.890 mmol). The NMR tube was sealed, removed from the glove box, shaken and placed in a preheated oil bath.

**General procedure for preparative-scale reactions:**

In a glove box, ammonium tetraphenylborate (28.3 mg, 0.08 mmol) was transferred to an oven-dried J. Young flask equipped with a magnetic stir bar along with the desired pyridine (3.36 mmol) and HBpin (0.73 mL, 5.04 mmol). Dry CH$_3$CN, heptane, or benzene (5ml) was then added outside of the glovebox. The reaction was then heated in an oil bath. Following heating the volatiles were removed in vacuo, and the remaining reaction mixture was suspended in dry pentane (5ml). The solution was then filtered through paper via a cannula filter into a pre-dried Schlenk flask. After removal of the pentane the 1,2- and 1,4-dihydropyridine products were retrieved as oils or waxy solids which can be purified further by reported methods if necessary. Due to the high moisture sensitivity of the products, the reaction was frequently contaminated with a small amount of pinBOH.
