Experimental details

Preparation of Ti wire supported TiO$_2$ nanotube anodes: The Ti wires ($\phi = 0.2$ mm) were thoroughly rinsed with acetone, ethanol and deionized water. Subsequently, they were polished for 10 min with mixture from HF (1 wt%), HNO$_3$ (7 wt%) and deionized water. The volume ratio was controlled at 1:4:5 for HF:HNO$_3$:H$_2$O. The Ti wire supported TiO$_2$ nanotubes were prepared by an anodic oxidation method using Ti wire as a working electrode, Pt sheet as a counter electrode, and mixture of 0.3 wt% NH$_4$F/ethanol/H$_2$O as a supporting electrolyte. The reaction was performed at 60 V for 5 h. Subsequently, the Ti wire supported TiO$_2$ nanotubes were annealed at 450 ºC for 3 h. The resultant anodes were further sensitized by immersing into a 0.5 mM ethanol solution of N719.

Preparation of counter electrodes: The feasibility of synthesizing CoSe counter electrode was confirmed by the following experimental procedures. In details, a mixing aqueous solution consisting of H$_2$SeO$_3$ and LiCl was made by agitating 0.0222 g of SeO$_2$ ultrafine powers and 0.6041 g of LiCl. 2 mM of stoichiometric CoCl$_2$ was dissolved in the above solution, and the total volume was adjusted to 100 mL by deionized water. In the case of Pt$_3$Ni electrode, the freshly-cleaned Ti wire was immersed into an aqueous solution containing 3 mM H$_2$PtCl$_6$, 1 mM NiSO$_4$ to produce Pt$_3$Ni electrode. The CoSe and Pt$_3$Ni counter electrodes were synthesized by a cyclic voltammetry method using Ti wire as a working electrode, Ag/AgCl as a reference electrode, and Pt sheet as a counter electrode. The deposition window ranged from -0.4 to 1.2 V at a scan rate of 50 mV s$^{-1}$ for four cycles. The reaction
temperature was controlled at room temperature. As a reference, the Pt electrode was also performed in 2 mM H$_2$PtCl$_6$ aqueous solution on Ti wire.

**DSSC assembly:** The optical fiber induced DSSC was fabricated by inserting a dye-sensitive TiO$_2$ nanotubes (on Ti) and a counter electrode (CoSe, Pt$_3$Ni or Pt) into a hollow optical fiber filled with an I$^/-$I$_3$ oxidation-reduction electrolyte. Subsequently, the LPP phosphors were coated on the external surface of hollow optical fiber. The ends were sealed with an ethylene-vinyl acetate copolymer. Finally, the whole device was inserted into a transparent quartz tube. The redox electrolyte consisted of 100 mM of tetaethylammonium iodide, 100 mM of tetramethylammonium iodide, 100 mM of tetrabutylammonium iodide, 100 mM of NaI, 100 mM of KI, 100 mM of LiI, 50 mM of I$_2$ and 500 mM of 4-tert-butyl- pyridine in 50 mL acetonitrile. The ethylene vinyl acetate copolymer was heated to its molten state and then injected into the one ends of tubes for consolidation.

**Electrochemical characterizations:** The electrochemical performances were recorded on a conventional CHI660E setup comprising an Ag/AgCl reference electrode, a CE of Pt sheet, and a working electrode of Ti wire CE. The cyclic voltammetry (CV) curves were recorded in a supporting electrolyte consisting of 50 mM LiI, 10 mM I$_2$ and 500 mM LiClO$_4$ in acetonitrile. EIS measurements of the DSSCs were also carried out in a frequency range of 0.1 Hz~10$^5$ kHz and an ac amplitude of 10 mV at room temperature.

**Photovoltaic measurements:** The photovoltaic test of the optical fiber induced DSSC was carried out by measuring the photocurrent-voltage ($J-V$) characteristic curves
using a CHI660E Electrochemical Workstation by illuminating hollow optical fiber by a simulated solar light from a 100 W Xenon arc lamp (XQ-500 W) in ambient atmosphere. The incident light intensity was controlled at 100 mW cm\(^{-2}\) (calibrated by a standard silicon solar cell). The active area for calculating \(J_{sc}\) and \(\eta\) was the geometric project area of photoanode, therefore it was the diameter \((\phi = 0.2 \text{ mm})\) of Ti wire. The fill factor \((FF)\) and power conversion efficiency \((\eta)\) was calculated according to the equations:

\[
FF = \frac{P_{\text{max}}}{J_{sc} \times V_{oc}} = \frac{J_{\text{max}} \times V_{\text{max}}}{J_{sc} \times V_{oc}}
\]

\[
\eta \% = \frac{P_{\text{max}}}{P_{\text{in}}} \times 100\% = \frac{J_{sc} \times V_{oc} \times FF}{P_{\text{in}}} \times 100\%
\]

where \(J_{sc}\) is the short-circuit current density (mA cm\(^{-2}\)), \(V_{oc}\) is the open-circuit voltage (V), \(P_{\text{in}}\) is the incident light power, \(P_{\text{max}}\) in the maximum power output, \(J_{\text{max}}\) (mA cm\(^{-2}\)) and \(V_{\text{max}}\) (V) are the current density and voltage at the point of maximum power output in the \(J-V\) curves, respectively.

**Other characterizations:** X-ray diffraction (XRD) profile of the resultant TiO\(_2\) nanotubes was recorded on an X-ray powder diffractometer (X'pert MPD pro, Philips, Netherlands) with Cu K\(\alpha\) radiation \((\lambda = 1.542 \text{ Å})\) in the 2\(\theta\) range from 20-70 °C operating at 40 kV accelerating voltage and 40 mA current.
