1. Experimental section

1.1 Synthesis

\[\text{[Mo}_3\text{S}_{13}]^{2-}\text{ nanoclusters}\]

The thiomolybdate \((\text{NH}_4)_2\text{Mo}_3\text{S}_{13}\cdot x\text{H}_2\text{O} \ (x=0-2)\) was prepared by the method outlined by Müller et al. briefly, 4.0 g of \((\text{NH}_4)_6\text{Mo}_7\text{O}_{24}\cdot 4\text{H}_2\text{O}\) was dissolved in 20 mL of water in an Erlenmeyer flask. An ammonium polysulfide solution (120 ml, 25 wt%) was added and the flask was covered with a watch glass. The solution was then kept on an oil bath (96 °C) for five days without stirring. Dark-red crystals of \((\text{NH}_4)_2\text{Mo}_3\text{S}_{13}\cdot x\text{H}_2\text{O}\) precipitated and were removed by filtering, followed by washing successively with water and ethanol. To remove excess sulfur, the \((\text{NH}_4)_2\text{Mo}_3\text{S}_{13}\cdot x\text{H}_2\text{O}\) crystals were first heated in hot toluene (80 °C) for 2-4 h followed washed by dimethylsulfoxide (DMSO) for several times. Finally, the crystals were dried in air and stored in darkness.

Colloidal MoS\(_2\) nanoparticles

Colloidal MoS\(_2\) nanoparticles were prepared by a simple solvothermal method according to the reported procedure in literature.\(^{S1}\) In brief, \((\text{NH}_4)_2\text{MoS}_4\) (12.5 μmol) was dissolved in methanol (25 mL) containing \(\text{N}_2\text{H}_4\text{H}_2\text{O}\) (50%, 0.1 mL) and an appropriate amount of poly(viny1pyrrolidone) (PVP, K30). The molar ratio of PVP (monomeric unit) to MoS\(_2\) is 20. The solution was added to a Teflon-lined stainless steel autoclave with a capacity of 50 mL and then heated at 423 K for 3 h to obtain the colloidal MoS\(_2\). The as-prepared colloidal MoS\(_2\) was directly used for following photocatalytic hydrogen evolution reaction without further treatment.

1.2 Characterization

X-ray diffraction (XRD) patterns were investigated with a Rigaku B/Max-RB diffractometer with a nickel filtrated Cu Kα radiation. X-ray photoelectron spectroscopy (XPS) measurements of the samples were performed on a K-Alpha surface analysis (Thermo Scientific) using X-ray monochromatization. Ultraviolet-visible (UV-vis) transmission spectroscopy was performed using a Shimadzu UV-
1800 spectrophotometer. Photoluminescence spectra were determined by a Horiba Scientific FluoroMax-4 spectrofluorometer. The fluorescence decay times were measured using the Horiba Jobin Yvon Data Station HUB operating in time-correlated single photon counting mode (TCSPC) with the time resolution of 200 ps. Nano LED diode emitting pulses at 370 nm with 1 MHz repetition rate was used as an excitation source. Light-scattering Ludox solution was used to obtain the instrument response function (prompt). The time ranges are 0.055 ns/channel in 4096 effective channels. Horiba Jobin Yvon DAS6 fluorescence decay analysis software was used to fit the model functions to the experimental data.

1.3 Electrocatalytic hydrogen evolution reactions

The electrochemical measurements were carried out in a standard three-electrode electrochemical set-up using a CHI660E potentiostat. The saturated Ag/AgCl and graphite rod were used as reference electrode and counter electrode, respectively. The working electrodes were prepared by drop-casting \([\text{Mo}_3\text{S}_{13}]^{2-}/\text{CH}_3\text{CN}\) solution onto the carbon paper (HESEN, HCP030P, thickness, 0.3 mm). Carbon paper were electrochemically active at 1.65 V vs. Ag/AgCl for 2 min in a phosphate buffer (pH 7) prior to the \([\text{Mo}_3\text{S}_{13}]^{2-}\) deposition.\(^2\) The loading amount of \([\text{Mo}_3\text{S}_{13}]^{2-}\) on carbon paper was controlled to be 10 nmol cm\(^{-2}\). The electrocatalytic activity of \([\text{Mo}_3\text{S}_{13}]^{2-}\) towards HER was examined by obtaining polarization curves using linear sweep voltammetry (LSV) at a scan rate of 1 mV s\(^{-1}\) in a 0.5 M H\(_2\)SO\(_4\) solution. All the applied potentials are reported as reversible hydrogen electrode potential scale using \(E\) (vs. RHE)=\(E\) (vs. Ag/AgCl)+0.2142 V after IR correction. Potentiostatic EIS was used to determine the uncompensated solution resistance (\(R_s\)). The reference electrode was calibrated with a Pt wire as the working electrode for the reversible hydrogen potential in the electrolyte solution purged with N\(_2\) for 30 min and saturated high purity H\(_2\) prior to the measurements.\(^3\)

1.4 Photocatalytic hydrogen evolution reactions
The photocatalytic hydrogen production experiments were performed in a sealed Pyrex reactor (250 mL) with a top flat quartz window for light irradiation and a silicone rubber septum was fixed on its side for sampling produced H\textsubscript{2} in the headspace of reaction cell. A 300 W Xe lamp (CEL-HXF300) equipped with an optical 420 nm cut-off filter was used as light source. In a typical experiment, Ru(bpy)\textsubscript{3}Cl\textsubscript{2} and the [Mo\textsubscript{3}S\textsubscript{13}]\textsuperscript{2-} catalyst were added to a mixed solution of CH\textsubscript{3}CN/H\textsubscript{2}O (9/1) containing 100 mM H\textsubscript{2}A with magnetic stirring. Before irradiation, the reaction system was thoroughly degassed by evacuation. The reaction solution was continuously stirred and maintained at 304 K by a flow of cooling ethanol. The amount of evolved H\textsubscript{2} was determined using a gas chromatograph (Tech comp; GC-7890II) with a thermal conductivity detector, a 5 Å molecular sieve column, and with N\textsubscript{2} as carrying gas.
