Supplementary information
General considerations

2,5-diformylfuran was synthesised according to an already reported procedure. All reagents were provided by Fischer Scientifique or accros chemicals and used without purification. Solvent were used as received. Raney Nickel (activated, 50% in water) was stored for 1 year and not reactivated before use.

All intermediary compounds were characterised by $^1$H and $^{13}$C NMR without purification. Final products were dried for 72 h at 40 °C under vacuum (0.1 mbar) before characterisation ($^1$H, $^{13}$C, IR, HRMS).

$^1$H and $^{13}$C NMR analysis were performed using a 250 MHz Brucker spectrometer. NOE spectra were performed using a 500 MHz Advance Brucker apparatus. Surface tension measurements were determined by AgroIndustrie recherches et Développements.

Synthesis of imines

The amine (2 equivalents, 16 mmol) is added to a stirred solution of DFF (1 g, 8 mmol) in ethanol (10 mL). The mixture is stirred for 4 h and diluted with water. The product is extracted with ethyl acetate (3*50 mL). The organic fractions are dried with MgSO$_4$, filtered and concentrated under vacuum.

Synthesis of amines

The crude imines are dissolved in ethanol (10 mL/g) and NaBH$_4$ (610 mg, 16 mmol) is added at 0 °C (ice bath). After the addition of NaBH$_4$, the ice bath is removed and the mixture is stirred 4h. Hydride excess is quenched by water addition and the product is extracted with ethyl acetate (3*50 mL). The organic fraction are dried with MgSO$_4$, filtered and concentrated under vacuum.

Reduction of furanic ring

The crude amines are dissolved in ethanol (10 mL/g) and Raney Nickel is added (1.7 mL of a 50% water solution, washed with 3*5 mL of ethanol). The Parr reactor is sealed and pressurised with

---

hydrogen (15 bars, 50 °C). The mixture is stirred overnight. After completion, the mixture is cooled to room temperature and hydrogen is carefully evacuated. Raney Nickel is filtered off and the product is obtained by vacuum evaporation of ethanol.

Synthesis of benzyl esters

The crude tetrahydrofuranic compounds are dissolved in ethanol (10 mL/g). The solution is cooled down to 5 °C and benzylacrylate is added (2.2 equivalents). The solution is stirred for 24 h and then concentrated under vacuum. The esters are purified using silica gel chromatographic column with petroleum ether/ethyl acetate (95/5 to 75/25).

Deprotection of benzyl esters

The pure benzyl esters are dissolved in ethanol (10 mL/g) in the presence of Pd/C (5 mol%). The mixture is stirred 12 h under hydrogen (balloon) and the catalyst is filtered off. Vacuum elimination of the solvent yield the final product. Before the determination of the activity of these compounds, they are purified using silica gel chromatography with petroleum ether/methanol (80/20 to 100% methanol) as eluent.

Determination of surface tensions and critical micellar concentrations

Surface tensions ($\gamma$) of aqueous surfactant solutions were recorded by a Wilhelmy-type surface balance (Kruess K100MK2) equipped with a dosimeter (700 dosino, Metrohm). CMC values were determined by the cross-section of both extreme tangential straight lines to the curves and adjusted if a clear break of $\gamma$-logC (C is mass concentration) curves appeared. Measurements were conducted at 25 °C and pH was specified in figures.

Determination of wetting power

Wetting power was investigated following the Draves test (AFNOR NTF 73-406 standard, 1 g L$^{-1}$ at 25 °C). Wetting power is defined as the required time to observe a cotton sink when this latter is immersed in a surfactant solution. The given value is average value obtained after three replicates.

Determination of antifungal properties

The antifungal activity was investigated against *Fusarium graminearum*. The tests were carried out by insemination of 30 microliters of a solution containing *F. graminearum* (2.10$^4$ spores/mL) mixed with the desired test concentration of gemini surfactant in Petri dishes containing PDA. The plates were sealed and incubated in the dark at 22°C. Control samples with *F. Graminearum* in PDA and distilled water were subjected to the same treatments. The effectiveness of the treatments was evaluated by measuring the average diametric growth of the colonies after 96 hours after the inoculum. The percentage of inhibition was calculated according to Wang et al.$^2$
