GlyAlaPhen
1. General procedures

Solvents were distilled from appropriate drying agents shortly before use. TLC was carried out on DC-plastikfolien Kieselgel 60 F\textsubscript{254} and preparative thick layer (2 mm) chromatography was done on Merck 60 F\textsubscript{254}. Microwave assisted reaction was conducted in a borosilicate glass vials sealed by reusable snap-cap with PTFE coated silicone septum. The microwave heating was performed in the Anton Paar microwave synthesis reactor Monowave 300. Reaction mixtures were stirred with a magnetic stir bar during the irradiation. The temperature, pressure and irradiation power were monitored during the course of the reaction. After completed irradiation, the reaction tube was cooled with high-pressure air until the temperature had fallen below 55 °C (ca. 1 min). IR spectra were obtained as KBr pellets on a Perkin–Elmer 297 spectrophotometer. \textsuperscript{1}H and \textsuperscript{13}C NMR spectra were recorded in DMSO–\textsubscript{d\textsubscript{6}} or CDCl\textsubscript{3} on Bruker AV 300 and 600 MHz spectrometers using TMS as the internal standard. The assignment of C-atoms and protons were confirmed on the basis of 2D NMR HETCOR, COSY, and NOESY. Chemical shifts (\(\delta\)) are expressed in ppm, and \(J\) values in Hz. Signal multiplicities are denoted as s (singlet), d (doublet), t (triplet), q (quartet) and m (multiplet). High resolution mass spectra (HRMS) were obtained using a MALDI-TOF/TOF mass spectrometer 4800 Plus MALDI TOF/TOF analyzer (Applied Biosystems Inc., Foster City, CA, USA). The electronic absorption spectra of newly prepared compounds, UV-Vis titration and thermal melting experiments were measured on a Varian Cary 100 Bio spectrometer. Fluorescence spectra were recorded on Varian Cary Eclipse fluorimeter. CD spectra were recorded on JASCO J815 spectrophotometer. UV-Vis, fluorescence and CD spectra were recorded using appropriate 1 cm path quartz cuvettes.

Materials

Starting compounds were prepared according to published procedures\textsuperscript{3,4}. Polynucleotides were purchased as noted: calf thymus (ct)-DNA, poly dGdC – poly dGdC, poly dAdT – poly dAdT, poly rA – poly rU, poly rA and poly rU (Sigma) and dissolved in sodium cacodylate buffer, \(i = 0.05\) mol dm\textsuperscript{-3}, pH=7.0. The calf thymus (ct-) DNA was additionally sonicated and filtered through a 0.45 μm filter\textsuperscript{5}. Polynucleotide concentration was determined spectrophotometrically as the concentration of phosphates\textsuperscript{6}. It is important to note that at experimental conditions (pH = 5) poly rA was protonated and formed double helix\textsuperscript{7}. The double-stranded conformation of poly rAH\textsuperscript{+}-poly rAH\textsuperscript{+} was obtained by lowering the pH value from the initial value of 7.0 to 5.0 and its concentration directly derived from the concentration of single stranded poly rA. The formation of ds-poly rAH\textsuperscript{+}-poly rAH\textsuperscript{+} was confirmed by CD and thermal melting experiments.\textsuperscript{8,9}

UV/Vis, fluorescence and CD measurements

The measurements were performed by adding aliquots of DMSO stock solutions to the buffer solution (pH = 5, \(i = 0.05\) mol dm\textsuperscript{-3}, sodium cacodylate/HCl buffer, DMSO content of the final solutions <0.01%). Concentrations below \(4 \times 10^{-5}\) M were used for UV-Vis absorbance measurement to avoid intermolecular association. Under the experimental conditions used (concentration of compounds 1-4 \(\sim 2 \times 10^{-5}\) mol dm\textsuperscript{-3} for UV-Vis and \(\sim 2 \times 10^{-6}\) mol dm\textsuperscript{-3} for fluorescence) the absorbance and fluorescence intensities of 1-4 were proportional to their concentrations. Fluorimetric titrations were performed by adding portions of polynucleotide solution into the solution of the studied compound. Excitation wavelength of \(\lambda_{\text{exc}} \geq 300\) nm was used to avoid
absorption of excitation light caused by increasing absorbance of the polynucleotide. After mixing polynucleotides with studied compounds it was observed in all cases that equilibrium was reached in less than 120 seconds. In following 2-3 hours fluorescence spectra of complexes remained constant. Due to low concentrations of studied compounds and polynucleotides used in fluorimetric titrations no precipitation occurred. Emission was collected in the range $\lambda_{em}=470 – 700$ nm (for compounds 1 and 2) and $\lambda_{em}=330 – 550$ nm (for compounds 3 and 4). Fluorescence spectra were collected at $r < 0.3$ ($r = \frac{[\text{compound}]}{[\text{polynucleotide}]}$) to assure one dominant binding mode. Titration data obtained for ds-DNA and ds-RNA were processed by means of Scatchard equation and Global Fit procedure. Calculations gave values of ratio $n=0.1 \pm 0.05$, but for easier comparison all $K_s$ values were re-calculated for fixed $n=0.1$. Values for $K_s$ have satisfactory correlation coefficients ($>0.98$). In Scatchard equation values of stability constant ($K_s$) and ratio ($n=\frac{[\text{bound compound}]}{[\text{polynucleotide}]}$) are highly mutually dependent and similar quality of fitting calculated to experimental data is obtained for ±20% variation for $K_s$ and $n$; this variation can be considered as an estimation of the errors for the given binding constants.

CD experiments were performed by adding portions of compound stock solution into the solution of polynucleotide ($c \approx 2 \times 10^{-5}$ mol dm$^{-3}$). CD spectra with scanning speed of 200 nm/min. Buffer background was subtracted from each spectra, while each spectra was result of five accumulations. Examined compounds 1-2 are achiral and therefore do not possess intrinsic CD spectrum. Compounds compounds 3 and 4 were built by chiral amino acid building blocks and consequently have intrinsic CD spectrum of low intensity.

Thermal melting curves for ds-DNA, ds-RNA and their complexes with studied compounds were determined by following the absorption change at 260 nm a function of temperature. Absorbance scale was normalized. $T_m$ values are the midpoints of the transition curves determined from the maximum of the first derivative and checked graphically by the tangent method. The $\Delta T_m$ values were calculated subtracting $T_m$ of the free nucleic acid from $T_m$ of the complex. Every $\Delta T_m$ value here reported was the average of at least two measurements. The error in $\Delta T_m$ is ±0.5 °C.

**Cytotoxicity evaluation**

Cytotoxic effects on the normal and tumours cells’ growth were determined using the colorimetric methyltetrazolium (MTT) assay. Experiments were carried out on two tumour human cell lines (HeLa and CaCo-2) and on one canine cell line (MDCK I) as normal cells. The adherent cells, MDCK1, HeLa, and CaCO2, were seeded in 96 micro-well plates at a concentration of 2 × 104 cells per mL and allowed to attach overnight in a CO2 incubator (IGO 150 CELLiﬁe™, JOUAN, Thermo Fisher Scientiﬁc, Waltham, MA, USA). After 72 hours of exposure to tested compounds, the medium was replaced with 5 mg mL$^{-1}$ MTT solution and the resulting formazan crystals were dissolved in DMSO. To each well, 10% SDS with 0.01 mol L$^{-1}$ HCl was added to dissolve water-insoluble MTT-formazan crystals overnight. An Elisa microplate reader (iMark, BIO RAD, Hercules, CA, USA) was used for measurement of absorbance at 595 nm. All experiments were performed at least three times in triplicate. The percentage of cell growth (PG) was calculated using the following equation:

$$PG = \frac{(A_{\text{compound}} - A_{\text{background}})}{(A_{\text{control}} - A_{\text{background}})} \times 100$$

where $A_{\text{background}}$ at the adherent cells is the absorbance of MTT solution and DMSO; $A_{\text{background}}$ at the suspension cells is the absorbance of the medium without cells, but containing MTT and 10% SDS.
with 0.01 mol L⁻¹ HCl; and \( A_{\text{control}} \) is the absorbance of the cell suspension grown without tested compounds.

2. Spectroscopic properties of 1-4

Figure S1. UV-Vis spectra of 1-4 and reference 10, \( c=1 - 4 \times 10^{-5} \text{ M} \), pH = 5.0, Na-cacodylate buffer, \( l=0.05 \text{ M} \).

Figure S2. Fluorescence spectra of 1 and 2, \( c=2 \times 10^{-6} \text{ M} \), \( \lambda_{\text{exc}} = 280 \text{ nm} \), slit exc = 5 nm, slit em = 5 nm, pH = 5.0, Na-cacodylate buffer, \( l=0.05 \text{ M} \).
Figure S3. Fluorescence spectra of 3 and 4, $c=2 \times 10^{-6}$ M, $\lambda_{\text{exc}} = 250$ nm, slit exc = 5 nm, slit em = 5 nm pH = 5.0, Na-cacodylate buffer, $l=0.05$ M.

Figure S4. Influence of temperature increase ($T = 25^\circ C – 90^\circ C$) on fluorescence emission spectra of 1 (left) and 2 (right), $c=2 \times 10^{-6}$ M, $\lambda_{\text{exc}} = 280$ nm, pH = 5.0, Na-cacodylate buffer, $l=0.05$ M.

Figure S5. Influence of temperature increase ($T = 25^\circ C – 90^\circ C$) on fluorescence emission spectra of 3 (left) and 4 (right), $c=2 \times 10^{-6}$ M, $\lambda_{\text{exc}} = 250$ nm, pH = 5.0, Na-cacodylate buffer, $l=0.05$ M.

### 3.3. Circular dichroism (CD) experiments

CD spectroscopy was chosen to monitor conformational changes of polynucleotide secondary structure induced by small molecule binding.

Unlike 1 and 2, compounds 3, DS8 and 4 were built using chiral amino acid building blocks and consequently have intrinsic CD spectrum.

![Figure S 37. CD spectra of 3 and 4 (Na-cacodylate buffer, pH 5.0, I= 0.05 M)](image)

![Figure S 38. Changes in the CD spectrum of ct DNA upon addition of 1 (c (DNA) = 3 \times 10^{-5} \text{ mol dm}^{-3}) (left) and 2 (c (DNA) = 2 \times 10^{-5} \text{ mol dm}^{-3}) (right) at different molar ratios \( r = [\text{compound}] / [\text{polynucleotide}] \), pH = 5.0, sodium cacodylate buffer, \( I = 0.05 \) mol dm\(^{-3}\).](image)
Figure S39. Changes in the CD spectrum of ct DNA (c = 2 × 10⁻⁵ mol dm⁻³) upon addition of 3 (left) and 4 (right) at different molar ratios r = [compound] / [polynucleotide], pH = 5.0, sodium cacodylate buffer, l = 0.05 mol dm⁻³.

Figure S40. Changes in the CD spectrum of poly dAdT – poly dAdT (c = 2 × 10⁻⁵ mol dm⁻³) upon addition of 1 (left) and 2 (right) at different molar ratios r = [compound] / [polynucleotide], pH = 5.0, sodium cacodylate buffer, l = 0.05 mol dm⁻³.

Figure S41. Changes in the CD spectrum of poly dAdT – poly dAdT (c = 2 × 10⁻⁵ mol dm⁻³) upon addition of 3 (left) and 4 (right) at different molar ratios r = [compound] / [polynucleotide], pH = 5.0, sodium cacodylate buffer, l = 0.05 mol dm⁻³.
Figure S 42. Changes in the CD spectrum of poly dGdC – poly dGdC (c = 2 x 10^{-5} mol dm^{-3}) upon addition of 1 (left) and 2 (right) at different molar ratios \( r = \text{[compound]} / \text{[polynucleotide]} \), pH = 5.0, sodium cacodylate buffer, \( I = 0.05 \) mol dm^{-3}.

Figure S 43. Changes in the CD spectrum of poly dGdC – poly dGdC (c = 2 x 10^{-5} mol dm^{-3}) upon addition of 3 (c (DNA) = 2 x 10^{-5} mol dm^{-3}) (left) at different molar ratios \( r = \text{[compound]} / \text{[polynucleotide]} \), pH = 5.0, sodium cacodylate buffer, \( I = 0.05 \) mol dm^{-3}.

Figure S 44. Changes in the CD spectrum of poly rA-poly rU (c = 3 x 10^{-5} mol dm^{-3}) upon addition of 1 (left) and 2 (right) at different molar ratios \( r = \text{[compound]} / \text{[polynucleotide]} \), pH = 5.0, sodium cacodylate buffer, \( I = 0.05 \) mol dm^{-3}.
Figure S 45. Changes in the CD spectrum of poly rA-poly rU (c = 3 × 10^{-5} \text{ mol dm}^{-3}) upon addition of 3 (left) and 4 (right) at different molar ratios r = [compound] / [polynucleotide], pH = 5.0, sodium cacodylate buffer, l = 0.05 \text{ mol dm}^{-3}.

Figure S 46. Changes in the CD spectrum of poly rAH*-poly rAH* (c = 2 × 10^{-5} \text{ mol dm}^{-3}) upon addition of 1 (left) and 2 (right) at different molar ratios r = [compound] / [polynucleotide], pH = 5.0, sodium cacodylate buffer, l = 0.05 \text{ mol dm}^{-3}.

Figure S 47. Changes in the CD spectrum of poly rAH*-poly rAH* (c = 2 × 10^{-5} \text{ mol dm}^{-3}) upon addition of 3 (left) and 4 (right) at different molar ratios r = [compound] / [polynucleotide], pH = 5.0, sodium cacodylate buffer, l = 0.05 \text{ mol dm}^{-3}.
4. Biological Activity

Figure S 50. Dose-response profiles for compounds 1-4 tested in vitro on a human tumour cell lines HeLa, CaCo2, and normal epithelial cells (MDCK1). Data represents mean values ± standard deviation
(SD) of three independent experiments. Exponentially growing cells were treated during 72-hrs period. Cytotoxicity was analysed using MTT survival assay.

5. MM2 calculations

![Figure S 51 1-4 were submitted to MM2 calculations by a modified version of Allinger's MM2 force field, integrated into the ChemBio3D 11.0 programme, whereby obtained structures demonstrate the possible intramolecular aromatic stacking between phenanthridine and triazolyluracil.](image)

2 Dukši, Marko; Baretić, Domagoj; Čaplar, Vesna; Piantanida, Ivo., *European journal of medicinal chemistry*. 2010, 6, 2671-2676.

10 Precipitation even to a small degree causes stray light effects, which generate irreproducibility of spectra, very often a intensity decrease with time, and pronounced differences between spectra of samples staying longer time and those taken instantly after mixing. A. Slama-Schwok and J.-M. Lehn, *Biochemistry*, 1990, **29**, 7895-7903. and ref. cited therein.
