Table SI1. Average particle size for the MNPs doped with 2% Er$^{3+}$ after consecutive reaction steps evaluated by XRPD.
Figure SI2. Hydrodynamic average size measured by DLS for MNPs with 2% Er$^{3+}$.

Figure SI3. UC emission upon 980 nm excitation of the core SrF$_2$:YbTm NPs.
Figure S14. UC emission upon 980 nm excitation of the core@shell NPs, SrF₂:YbTm@Y. An increase in the 650 nm and 800 nm emission bands can be noticed, with an increase of the signal/noise ratio, due to an overall intensification of the emission.

Figure S15. UC emission upon 980 nm excitation of the core@shell@shell NPs, SrF₂:YbTm@Y@YbEr(1%)Nd. An increase in Tm³⁺ emission band at 460 nm can be noticed, probably due to the lower interaction of Tm³⁺ ions with the solvent, since Tm³⁺ ions are located only in the core of the MNPs. A typical Er³⁺ ions emission band can be seen at 550 nm, the low intensity is due to a quenching induced by the solvent.
Figure S16. Energy transfer and emission processes for the MNPs upon 980 nm excitation.

Figure S17. Energy transfer (ET) and emission processes for MNPs upon 806 nm excitation. Brown, ascending solid arrows represent laser excitation. Dotted descending black arrows represent non-radiative de-excitation. Descending solid arrows represent emission. Ascending dashed arrows represent energy absorption (ascending brown dashed arrows represent ESA of 806 nm radiation). Red dashed arrows represent ET. Blue dashed arrows represent Er$^{3+}$→Nd$^{3+}$ ET.
Figure S18. Thermometric measurements of the MNPs with different Er^{3+} concentration in the second shell. Er^{3+} 0.2% in a), 1% in b), 4% in c), 8% in d).
Figure SI9. MNPs NIR absorption (dashed line), and emission (solid line) upon 806 nm excitation. In the inset the Stark levels of the Yb$^{3+}$ ions are highlighted. An increasing thermal population of the 6 and 7 levels allows the increase of the Nd$^{3+}$→Yb$^{3+}$ back ET process.
