General methods and materials

All reagents were obtained from Sigma Aldrich, Alfa Aesar, Apollo Scientific or Acros Organics and used without further purification. All reactions were conducted in oven-dried glassware under an inert atmosphere of nitrogen unless not using anhydrous solvents. Anhydrous solvents were dried by pre-storing them over activated 3 Å molecular sieves before being passed through an activated alumina column on a solvent tower under N₂ pressure. ‘Petrol’ refers to light petroleum ether of boiling point 40-60 °C and was used as purchased. Solvents were evaporated at 40 °C under reduced pressure on a Büchi R-114 rotatory evaporator attached to a Vacuubrand CVC2 pump and a pressure control system. Concentrations (c) in the general procedures refer to the limiting reagent and are given in mmol/mL.

Analytical thin layer chromatography (TLC) was carried out on Merck aluminium foil backed sheets precoated with 0.2 mm Kieselgel 60 F₂₅₄. The eluent used is specified in each case. The spots were visualised by UV irradiation (λ 254 nm) and by staining with a KMnO₄ solution followed by heating. Retention factors (Rₛ) are quoted to the nearest 0.01. Flash column chromatography was performed on Kieselgel 60 silica gel (230-400 mesh particle size). The eluents are specified in each case.

Optical rotations were recorded at 25 °C on a Perkin-Elmer 241 polarimeter or Unipol L 2000 using the D line of sodium (589 nm) and a path length of 1 dm. Concentrations (c) are given in g/100 mL and specific rotations ([α]D₂₀) are quoted in 10⁻¹ deg cm² g⁻¹.

Melting points were measured using a Stuart Scientific SMP1 melting point instrument and are uncorrected.
Infrared spectra were recorded on a Bruker Tensor 27 FT-IR spectrometer equipped with an attached Pike Miracle attenuated total reflectance (ATR) module. Absorption maxima ($\nu_{\text{max}}$) are reported in wavenumbers (cm$^{-1}$) and only selected peaks are reported.

$^1$H NMR spectra were recorded on the following instruments: AVIII HD 400 (400 MHz) and AVII 500 (500 MHz). Chemical shifts ($\delta_{\text{H}}$) are reported in parts per million (ppm) downfield from TMS and are referenced to the residual $^1$H solvent peak. Coupling constants ($J$) are quoted in Hz. Data are reported as follows: chemical shift, integration, multiplicity (s = singlet, d = doublet, t = triplet, q = quartet and m = multiplet), coupling constant, and assignment. Two-dimensional COSY spectra were recorded on Bruker AVIII HD 400 (400 MHz) and AVII 500 (500 MHz) spectrometers, and NOE experiments were performed on a Bruker AVII 500 (500 MHz).

$^{13}$C NMR spectra were recorded on a Bruker AVIII HD 400 at 100.6 MHz and AVII 500 at 125.8 MHz with proton decoupling. Chemical shifts ($\delta_{\text{C}}$) are reported in ppm downfield from TMS and are referenced to the residual $^{13}$C solvent peak. Assignments of the spectra were made with HSQC and HMBC experiments, which were performed on a Bruker AVII 500 spectrometer.

Low resolution mass spectra ($m/z$) were recorded on a Fison Platform spectrometer using electrospray ionisation (ESI). Selected peaks are reported in Daltons and their intensities given as percentages of the base peak. High resolution mass spectra (HRMS) were recorded on a Bruker microTOF (ESI) or on an Agilent 7200 Q-TOF (CI). LC/MS spectra were recorded on a Bruker 9.4T FT-ICR-MS (ESI).

Crystals for X-ray crystallography were grown from slow vapour diffusion of petrol into a solution of the compound in EtOAc at room temperature.

**General procedure C: Aldol cyclisation of N-acyloxazolidines**

Sodium methoxide (1.05 eq) was added to a solution of N-acyloxazolidine (1.0 eq) in anhydrous MeOH (c 0.2), and stirring was continued at room temperature for 18 h. The reaction mixture was quenched with saturated aqueous NH₄Cl and extracted with Et₂O. The organic phase was washed with brine, dried over anhydrous Na₂SO₄ and concentrated in vacuo. The crude product was purified by flash column chromatography to give the bicyclic pyrrolidinone.

**Proteasome inhibition assay**

H460 cells were obtained from the ATCC cell bank, and KMS-12-BM from the DSMZ cell bank. The medium used for H460 cells was DMEM (10% FBS + Pen Strep), and RPMI (20% FBS + Pen Strep) for KMS-12-BM cells.

Proteasome activity was measured via the Promega Proteasome-Glo™ Chymotrypsin-like Cell based assay kit (G8660), in two different cell lines (H460 and KMS-12-BM), in a 96-well white walled plate. For H460 cells, 7.5 x 10^4 cells/per well were seeded overnight before performing the assay the next day. For KMS-12-BM cells, 1.5 x 10^5 cells/per well were seeded on the day of the experiment. Compounds at the required concentration were added in triplicate wells for 30 minutes before the assay was started via the addition of Proteasome-Glo reagent. Luminescence readings were taken after 15 minutes using an OMEGA POLARstar plate reader. Readings were normalised as a percentage of a control value obtained in the absence of compound. Values represent the mean of three separate measurements.
