General information:
Melting points measured on an Electrothermal 9100 apparatus. IR spectra were recorded as KBr pellets on a NICOLET FT-IR 100 spectrometer. $^1$H NMR (300 and 500 MHz) and $^{13}$C NMR (75 and 100 MHz) spectra were obtained using Bruker DRX-300 AVANCE and Bruker DRX-500 AVANCE spectrometers. All NMR spectra at room temperature were recorded in CDCl$_3$ and DMSO-$d_6$. Chemical shifts are reported in parts per million (δ) downfield from an internal tetramethylsilane reference. Coupling constants (J values) are reported in hertz (Hz), and spin multiplicities are indicated by the following symbols: s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet). Elemental analyses for C, H and N performed using a Heraeus CHN–O–Rapid analyzer. Mass spectra were recorded on a FINNIGAN-MATT 8430 mass spectrometer operating at an ionization potential of 70 eV. All chemicals were purchased from Merck or Aldrich and were
used without further purification. Due to very low solubility of the products 9h, no $^{13}$C NMR data were obtained for this product.

**Optimization of Reaction Conditions for Synthesis 9:**

Screening the various solvents revealed that only DMF and DMSO at heat condition afforded the desired product in moderate yield (Table S1, entries 1 and 2) under aerobic condition. Other solvents such as MeOH, THF, MeCN, and dioxane were completely ineffective (results not shown). Running the reaction under oxygen atmosphere did not improve the isolated yield relative to air atmosphere (entry 3). Next, it was found that under aerobic condition, among the range of the Cu$^{I}$ and Cu$^{II}$ salts (entries 1-9), only Cu(OAc)$_2$, CuSO$_4$.H$_2$O, and CuI could proceed the reaction to give 9a in moderate yield within 10 h (entries 1, 6, and 9). Using Cu(OAc)$_2$ under argon atmosphere led to 21% yield, while CuI showed completely to be unreactive (entries 10 and 11). The reactivity was improved by lowering the loading amount of Cu(OAc)$_2$ from 50 mol % to 10 mol % under air (entries 12-14). However, further decrease in the loading amount of the catalyst was undesirable (entry 15). Raising temperature to 100 °C deteriorated the reaction (entry 16). Significant improvement achieved by increasing the phenylboronic acid from 1 to 2 equiv (entry 17). As a result of this modification, the reaction time decreased to 1h. Interestingly, using scrupulously dried DMF caused dramatic decrease in yield (35 %, entry 18).

Gratefully, the reaction showed good compatibility with multi-component reaction by affording 9a in 80% yield (Scheme S1 and Table S1, entry 19). Therefore, due to the advantages of the multi-component reactions, the 10 mol% Cu(OAc)$_2$ in the presence of 2 equivalent phenylboronic acid at 70 °C under air atmosphere was selected for the synthesis of 9a (Table S1, entry 19). It is notable the EtOH is necessary for the reaction and a mixture of DMF-EtOH was selected as best solvent [1].

**Scheme S1.** One-pot synthesis of 9a

**Characterization of Cu-thiophene Complex (E):**

First, considering the general remarks about the reactivity of Cu$^1$ and Cu$^{II}$ salts under air (Table S1, entries 1, 6, and 9), low reactivity of Cu$^{II}$ and lacking the reactivity of Cu$^1$ under argon (Table S1, entries 10 and 11), following the progress of the reactions drawn our attention (Figure 1). As shown in Figure 1, the starting mixture containing CuI, aminothiophene, and PhB(OH)$_2$ readily involved complexation right after stirring under aerobic and heat condition (Figure 1, entry 1B). Then, upon elapsing time, the insoluble yellow participants gradually changed to a brownish-red solution within 1 h (entry 1C). In contrast, the reaction mixture remained intact under argon atmosphere, and no complexation observed (Figure 1, entry 2). TLC examination of this reaction did not show the presence of the desired adduct 9a even after prolonging the reaction time to 24 h (Table S1, entry 11). No complexation could account for the inefficiency of CuI (Cu$^1$) under inert condition.
(Table S1, entry 11). Using Cu(OAc)$_2$ under air led to the same sequence as CuI, involving rapid complexation and gradually dissolution of the complex (Figure 1, entry 3). Unlike CuI, using Cu(OAc)$_2$ under argon atmosphere led to Cu-complexion and following dissolution of the corresponding Cu-complex (Figure 1, entry 4). Finally, to gain knowledge on the structure of complex, a reaction containing Cu(OAc)$_2$/thiophene/air and without the presence of PhB(OH)$_2$ was performed (Figure 1, entry 4). The experiment showed that the readily formed Cu-complex remained intact even after a prolonged time. Therefore, we conclude that PhB(OH)$_2$ did not involve in the Cu-complex.

1) CuI under air:

2) CuI under argon:

3) Cu(OAc)$_2$ under air:

4) Cu(OAc)$_2$ under argon:

5) Cu(OAc)$_2$ under air in the absence of PhB(OH)$_2$:

Figure 1. Following the progress of the reaction mixture under different conditions: A) before stirring; B) heating after 1 min; C) heating after 1 h.
Further experiments revealed that Cu-complexion as an intermediate can take place for Cu$^{II}$ under both air and argon atmospheres. However, Cu-complexion for Cu$^{I}$ is only possible under air atmosphere. Also, it was found that the complexation reaction can occur in a wide range of solvents (MeOH, THF, MeCN, and dioxane) without the need of heat. However, conversion from intermediate (Cu-complex) to the target molecule is only possible by DMF or DMSO under heat condition. The experiments revealed that trying the reaction at room temperature is completely unfruitful. At this juncture, we recognized through this study that the suitable choice of the solvent, presence of heat and oxygen are critical for this transformation. We envisioned that characterization of the readily formed complex may give an important clue for mechanism elucidation. Therefore, we analyzed the in situ generated Cu-complex obtained from the three different conditions i) the mixture of CuI, aminothiophene and PhB(OH)$_2$ at heat condition in DMF under air atmosphere (Figure 1, entry 1B); ii) the mixture of Cu(OAc)$_2$, aminothiophene and PhB(OH)$_2$ at heat condition in DMF under argon atmosphere (Figure 1, entry 4B), and iii) the mixture of Cu(OAc)$_2$ and thiophene at heat condition in DMF under air atmosphere, and in the absence of PhB(OH)$_2$ (Figure 1, entry 5B). Upon formation the complex, the insoluble yellow particles were collected by filtration and washed thoroughly with water and DMF. The dried powder was then analyzed by powder x-ray diffraction (XRD; Figure 2). Interestingly, all of the three complexes showed exactly the same XRD patterns.

![Figure 2. XRD pattern of the complex from: a) CuI under air; b) Cu(OAc)$_2$ under argon; and c) Cu(OAc)$_2$ and thiophene without PhB(OH)$_2$ under air](image)

The results of XRD patterns were further confirmed by elemental analysis as all of the three complexes showed identical element contents. The obtained data demonstrated the presence of Cu and thiophene in 1:2 ratio (Table 4).

The IR spectroscopy results showed that two bands in 3289 cm⁻¹ and 3400 cm⁻¹ in free aminothiophene were replaced by one band in 3340 cm⁻¹ in Cu-complexes, indicating the conversion of NH₂ to NH as a result of complexation (Figure 2). More to the point, shifting the carbonyl vibrational frequency from 1590 cm⁻¹ in free aminothiophene to 1553 cm⁻¹ in Cu complexes implies that the bidentate coordination is in place.

**Figure 2.** Comparison between the IR spectrum of free thiophene (up) and thiophene Cu-complex (down)

Having clarified that common intermediate involves in different conditions, to get further insight about the mechanism of the reaction we investigated the coupling reaction of 1 equivalent of the Cu-complex afforded by aminothiophene and Cu(OAc)₂ with 4 equivalent of PhB(OH)₂ (corresponding to 1/2 ratio of aminothiophene and PhB(OH)₂ found as an optimal condition in Table S1, entry 17 and considering that 1 equivalent of Cu-complex delivers 2 equivalents of thiophene) under air and argon atmosphere.

a Reaction conditions: Cu complex (1 mmol, 1 equivalent), PhB(OH)₂ (4 mmol, 4 equivalent) in DMF (8 mL) at 70 °C for 24 h. b Isolated yield.

According to our experiment, the reaction afforded 19 % yield based on the equivalents of the thiophene in Cu complex under argon atmosphere. However, the yield increased to 44 % under air atmosphere.

From these experiments, we can conclude these deductions: 1) demonstrating that starting from CuI and CuII salts leads to pass the reaction from a common intermediate, having reactivity under
Cu\textsuperscript{I}/O\textsubscript{2}, Cu\textsuperscript{II}/O\textsubscript{2}, Cu\textsuperscript{II}/Ar conditions, lacking the formation of any complex under Cu\textsuperscript{I}/Ar, and more importantly lacking the reactivity under Cu\textsuperscript{I}/Ar implies that dimeric thiophene Cu(II) complex is the active catalytically species during the reaction cycle. It is believed that furnishing the moderate yield under Cu\textsuperscript{I}/O\textsubscript{2} condition is due to the primary oxidation of Cu\textsuperscript{I} (thiophene) complex to Cu\textsuperscript{II} (thiophene)\textsubscript{2} complex through an oxidative copper amination reaction [2]; 2) crucial importance of solvent and heat for progressing from Cu\textsuperscript{II} (thiophene) complex to next step, indicates that transmetallation with PhB(OH)\textsubscript{2} may be the rate-determining step in the reaction cycle; 3) the reaction proceed through disproportionation of Cu\textsuperscript{II} (thiophene)\textsubscript{2} to Cu\textsuperscript{III} (thiophene)\textsubscript{2}(phenyl) and Cu\textsuperscript{I} (thiophene) without the need of oxygen (Table S1, entry 10). Then, the monomeric Cu(I) species is re-oxidized by oxidative copper amination reaction in the presence of air, forming back the starting dimeric Cu(II) species. Otherwise, if the alternative Cu(I)/Cu(II)/Cu(0) or Cu(II)/Cu(0) involved in the catalytic cycle which in the absence of oxidizing agent could sustainably generate Cu(II) species, theoretically, the yield of \textit{9a} under Cu\textsuperscript{II}/Ar would be higher than 25% (Table S3, entry 1). Ortep Diagram of Compound 10a
Experimental Procedures for Synthesis Starting Materials 11, 12 and 13:

General Procedure for Synthesis 11:
A solution of the desired ketene dithioacetal including 2-di(methylsulfanylmethylene malononitrile, methyl 2-cyano-3,3-di(methylsulfanyl)acrylate, ethyl 2-cyano-3,3-di(methylsulfanyl)acrylate or 2,2-di(methylsulfanyl)-1-phenylvinyl cyanide (0.25 mmol) and phenylhydrazine (0.027 g, 0.25 mmol) in 1 mL of MeOH was refluxed for 3 h. After evaporation of the solvent, the residue was recrystallized by MeOH to give pyrazole 11 [4].

General Procedure for Synthesis 12:
Ethyl 3-amino-4-cyano-5-(methylthio)thiophene-2-carboxylate (8) (0.242 g, 1 mmol) was stirred in H$_2$SO$_4$ (95-98 %, 0.5 mL) at room temperature for 5h. Then, the reaction mixture was poured into cool water and the precipitates were filtered. The afforded solid was recrystallized by EtOH to give Yellow powder 12 (m.p: 184-185 °C, 0.211 g, yield: 81 %) [5].

General Procedure for Synthesis 13:
Sodium hydride (0.024 g, 1 mmol,) is added portionwise to a solution of 4-amino-5-benzoyl-2-methylsulfanyl-3-thienyl cyanide (0.274 g, 1 mmol) in 3 mL of DMF whilst stirring at room temperature. Stirring continued until the formation of gas has stopped. Then, methyl iodide (0.142 g, 1 mmol,) was added dropwise, and the reaction mixture is stirred for 12 hours at room temperature. For work-up, the reaction mixture was poured into water, and the resulting mixture was extracted by EtOAc. After drying the organic phase over sodium sulphate, the solvent is distilled off under reduced pressure to afford pale yellow solid 13 (m.p: 98-99 °C, 0.210 g, yield: 73 %) [6].
