Materials and characterizations

All reagents were purchased from Sigma Aldrich and used without further purification unless otherwise noted. Anhydrous $N,N$-dimethylformamide is prepared from MB-SPS solvent purifying system. $^1$H and $^{13}$C NMR spectra were recorded on a Brucker ARX 400 at 293 K with deuterized chlorofrom as solvent. Size exclusive chromatography (SEC) was performed in tetrahydrofuran or trichlorobenzene under room temperature or $140^\circ$C with calibration curve based on polystyrene standards. UV-vis-NIR spectra were measured with an Agilent Technologies Cary 6000i UV-Vis-NIR spectrophotometer (300-1300 nm). All solution spectra were collected in chloroform and thin film spectra from drop-casted samples on glass substrate.

Organic field-effect transistors fabrication

For FET devices, a heavily n-doped Si wafer with a 300-nm SiO$_2$ surface layer (capacitance of 11 nF/cm$^2$) was employed as the substrate with Si wafer serving as the gate electrode and SiO$_2$ as the dielectric. The gold S/D electrodes were sputtered and patterned by photolithography technique. The device channel length was 20 μm, and the channel width was 1400 μm. For the octadecyltrichlorosilane (OTS) modification, the silicon wafer (with Au bottom contact) was first cleaned with hot piranha solution (H$_2$SO$_4$ (98%); H$_2$O$_2$ (30% water solution) = 7 : 3). It was then further subjected to sonication sequentially in water and acetone for 6 min each. After drying at an oven, the silicon wafer was then put in a petri dish with a small drop of OTS. The dish was then covered and heated in a vacuum oven at 120 °C for 3 hours resulting in the formation of an OTS self-assembled monolayer on the surface. The OTS modified substrates were
rinsed successively with hexane, ethanol, and chloroform, and dried by nitrogen. The semiconductor layer was deposited on the OTS-treated Si/SiO$_2$ substrates by spin coating 10 mg/mL semiconductor solution in chloroform with spin speed of 2000 r.p.m. and spin time of 60 s. The devices were then annealed in nitrogen glovebox at 120 °C for 10 minutes.

**Device characterization**

Device characterization was carried out using Keithley 4200 in ambient air. The field-effect mobility was calculated in the saturation regime by using the equation $I_{DS} = (\mu WC_i/2L)(V_G - V_T)^2$, where $I_{DS}$ is the drain–source current, $\mu$ is the field-effect mobility, $W$ is the channel width, $L$ is the channel length, $C_i$ is the capacitance per unit area of the gate dielectric layer, $V_G$ is the gate voltage, and $V_T$ is the threshold voltage.

**General method for polymerization**

General method for the direct arylation polymerization.

To a Schlenk tube was added the monomer TBII-Br, catalyst, ligand, base, additive, then vacuum for about 5min and purge with N$_2$, and repeated the vacuum and purge for three times. After then, added the degassed solvent into the tube and heated in oil bath. When the reaction was done added chloroform and water into the tube collected the organic phase and precipitated with methanol. The precipitate solid was submit to soxhlet extraction with methanol, acetone, hexane and chloroform, collected the hexane fraction and chloroform fraction, precipitate with methanol to get the solid product.
