Experimental Section

Materials

Butyl methacrylate (BuMA, Sigma-Aldrich) was deinhibited by passing through a column of basic alumina. 4-Cyano-4-[(dodecylsulfanylthiocarbonyl)sulfanyl] pentanoic acid (CDTPA, Boron Molecular) was used as received. Hexadecane (HD, Sigma-Aldrich) and sodium dodecyl sulfate (SDS, Sigma-Aldrich) was used as received. MilliQ water was used for miniemulsion experiments.

Characterizations

Conversion was measured using gravimetry by drying samples in a vacuum oven at 40 °C. The molecular weight and molecular weight distribution was measured by gel permeation chromatography (GPC). Tetrahydrofuran (HPLC grade, 0.05% w/v 2,6-dibutyl-4-methylphenol (BHT)) was used as the eluent at 40 °C and at a flow rate of 1 mL/min. The GPC system was comprised of a Shimadzu SIL-10AD auto-injector, a Polymer Laboratories 5.0 μm bead-size guard column (50x7.5 mm²), 4 linear PL (Styrage) columns (10⁵, 10⁴, 10³ and 500 Å) and an RID-10A differential refractive index (RI) detector and UV-Vis detector.
Droplet/particle diameters and their distributions were characterized by dynamic light scattering (DLS) via a Malvern Zetasizer Nano running DTS software. The instrument was comprised of a 4 mW He-Ne laser operating at a wavelength of 633 nm and an avalanche photodiode (APD) detector with the angle set at 173°.

**Bulk polymerizations**

In a typical procedure, CDTPA (0.2539 g, $6.29 \times 10^{-4}$ mol) was added to a 21 mL (d = 2 cm) borosilicate glass vial equipped with a magnetic stirrer. Butyl methacrylate (8.4909 g, $6.29 \times 10^{-2}$ mol) was then added to the vial and the vial was subsequently sealed with a rubber septum and bubbled with N$_2$ gas in an ice bath for 30 mins. Following the deoxygenation process, the reaction vessel was placed into the visible light reactor setup shown below and polymerization was started by turning on the light (stirred at 400 rpm).

For batch reactions, the polymerization was stopped by turning the light off and exposing the reaction mixture to oxygen after the predetermined exposure time. For kinetic experiments, sampling was performed at predetermined exposure times using a gas-tight syringe, filled with N$_2$, directly from the reaction vessel without switching the light off. The aliquots were first dried in a vacuum oven (40°C, 48 h) for gravimetric analysis. The dried samples were further analysed by GPC.

**Miniemulsion polymerizations**

For the preparation of miniemulsions, the organic and aqueous phases were first prepared separately. For all miniemulsion reactions presented in this work, the monomer was fixed at 0.5 g (5 wt% relative to the aqueous phase which was fixed at 10 g). The hydrophobe hexadecane and the RAFT agent, CDTPA were also fixed at 0.04 g (8 wt% relative to the monomer) and 0.014 g (for DP$_{\text{target}} = 100$) respectively. The aqueous phase was prepared by adding the surfactant, SDS (which ranged from 0.02 g (4 wt%) to 0.06 g (12 wt%), to a Cospak bottle, followed by the addition of deionized milliQ water (10g). In a separate glass vial, CDTPA (0.014 g, $3.52 \times 10^{-5}$ mol), hexadecane (0.04 g) and butyl methacrylate (0.5 g, $3.52 \times 10^{-3}$ mol) were mixed and then added to the aqueous phase. The 2 phase mixture was subsequently homogenized using an ultrasonic probe (Branson 450) for 10 mins at an amplitude of 50% whilst being cooled by an ice bath. The miniemulsion was allowed to mature for 30 mins before an aliquot was removed for DLS analysis. Thereafter, 10 mL of the miniemulsion was transferred to a 21 mL glass vial equipped with a magnetic stirrer bar and then sealed with a septum and subsequently bubbled with N$_2$ for 30 mins in an ice bath. The deoxygenated reaction vessel was then placed in the visible light reactor and polymerization was started by turning on the light.

For batch reactions, the polymerization was stopped by switching off the light and exposing the miniemulsion to air. Kinetic sampling was performed using a gas-tight syringe filled with N$_2$, and samples were removed directly from the reaction vessel without turning the light source off.

Samples were first analysed by DLS and then dried in a vacuum oven (40°C, 48 h) for gravimetric analysis. The dried samples were further analysed by GPC.
Reactor Setup

The reactor setup shown below consists of an LED strip (2.5 m, 14.4 W/m, 25 leds, $\lambda_{\text{max}} = 530$ nm) wrapped on the inside of an oil bath. The reaction vessel was placed in the center of the reactor (c.a. 6 cm from the LED strip).

**Calculation of free surfactant concentration**

**Method**

1. For each surfactant concentration studied, the total interfacial area was calculated based on arbitrary initial droplet diameters using the following formulae:

\[
A (\text{interfacial area}) = n_d \cdot \pi \cdot D^2
\]

\[
n_d (\text{number of monomer droplets}) = \frac{(\text{total volume})}{\frac{4}{3} \cdot \pi \cdot r^3}
\]

Where, and $D$ = avg. droplet diameter

2. From the obtained interfacial area ($A$), the number of SDS molecules at the interface was calculated using:

\[
N (\text{mol of SDS at interface}) = A \cdot \Gamma_{\text{cmc}}
\]

Where, $\Gamma_{\text{cmc}}$ (surface conc. of SDS at interface) $= 4.17 \times 10^{-10}$ mol $\cdot$ cm$^{-2}$

3. To obtain the amount of free surfactant, the value obtained from step 2 was subtracted from the actual surfactant amount used.
Comments

The above calculations are based on a surface concentration of SDS at a styrene water interface as reported by Chang et al.\textsuperscript{1} Figure S5 presents the results of these calculations. The DLS results (Figure 4, main text) indicate that the initial droplet diameters are below 100 nm at surfactant concentrations used in the study. At or below this diameter, there are significant amounts of free surfactant at surfactant concentrations of 12 and 10 wt\%. However, the calculated surfactant concentration is below the cmc of SDS (8 mM).\textsuperscript{2} It is important to note that these calculations do not take into account the surface activity of the RAFT agent and its impact on the SDS concentration at the interface.
