1-1. Materials

(S)-epichlorohydrin (>99.0%, enantiomeric excess (e.e.) >99.0%) was purchased from Sanyo Fine Co., Ltd., and used as received. (RS)-epichlorohydrin (>99.0%), 2-methoxyethanol (>99.0%), 2-ethoxyethanol (>99.0%), ethylene glycol monopropyl ether (>98.0%), diethylene glycol monomethyl ether (99.0%), diethylene glycol monoethyl ether (>99.0%), and boron trifluoride – ethyl ether complex (BF$_3$-Et$_2$O; >98.0%) were purchased from Tokyo Chemical Industry Co., Ltd. (TCI) and used as received. n-Butanol (>98.0%; n-BuOH), glycidyl methyl ether (>85%; MeGE) and glycidyl isopropyl ether (>96.0%; iPrGE) were purchased from TCI and purified by distillation under vacuum over calcium hydride, which were then stored under an argon atmosphere. t-Bu-P$_4$ (in n-hexane as 1.0 mol L$^{-1}$ solution) was purchased from the Sigma-Aldrich Chemicals Co. and used as received. Commercially-available dry toluene (Kanto Chemical Co., Inc., >99.5%, water content, <0.001%) was further purified by an MBRAUN MB SPS Compact solvent purification system equipped with a MB-KOL-C column and a MB-KOL-A column. 2-(2-(2-Methoxyethoxy)ethoxy)ethyl glycidyl ether (MeEO$_3$GE) was prepared according to a reported method and purified by distillation under vacuum over calcium hydride.$^1$

1-2. Instruments

The polymerization was carried out in an MBRAUN stainless steel glovebox equipped with
a gas purification system (molecular sieves and copper catalyst) in a dry argon atmosphere (H$_2$O, O$_2$ <1 ppm). The moisture and oxygen contents in the glovebox were monitored by an MB-MO-SE 1 moisture probe and an MB-OX-SE 1 oxygen probe, respectively. The optical rotations were measured at 25 °C by a Jasco DIP-1000 digital polarimeter equipped with a sodium lamp (589 nm) using a 50 mm path length cell. The SEC in THF was performed at 40 °C using a Shodex GPC 101 system (DU-H 2130 Intelligent HPLC pump, RI-71S Intelligent RI detector, and ERC-3125) equipped with a Shodex K-G guard column (4.6 mm × 10 mm; particle size, 8 μm) and two Shodex K-805L columns (linear; particle size, 10 μm; 8.0 mm × 300 mm; exclusion limit, 4 × 10$^4$) at the flow rate of 1.0 mL min$^{-1}$. The number-average molecular weight ($M_{n,SEC}$) and molecular weight distribution ($M_w/M_n$) of the polymers were calculated on the basis of a polystyrene (PSt) calibration. The optical purity of the monomers was determined by a chiral HPLC analysis using a DAICEL CHIRALPAK IC column (flow rate, 1.0 mL min$^{-1}$; solvent, n-hexane/EtOH = 95/5 (v/v), temp., 25 °C; detector, RI). The $^1$H (400 MHz) and $^{13}$C NMR (100 MHz) spectra were recorded using a JEOL ECS400 instrument, and the chemical shifts are referenced to the internal standard of tetramethylsilane (0 ppm). The thermal properties of the samples in the bulk were measured during the second heating under a nitrogen atmosphere from −100 to 100 °C at the heating rate of 10 °C min$^{-1}$ and cooling rate of −10 °C min$^{-1}$ by a Bruker AXS DSC 3100 differential scanning calorimeter. The turbidimetry analysis was performed at $\lambda = 500$ nm with the heating and cooling rates of 1.0 °C min$^{-1}$ using a Jasco V-550 spectrophotometer equipped with a Jasco ETC-505T
temperature controller. For the turbidity measurement, the sample was dissolved in deionized water, then the solution degassed at room temperature for 30 min. The dynamic light scattering (DLS) measurement was performed using a Delsa Nano HC Zeta Potential and Submicron Particle Size Analyzer with a solid state laser ($\lambda = 658$ nm, $\theta = 15^\circ$).

5. Additional Discussion for Tacticity Effects on Thermal Properties

The lack of the tacticity effect on the thermoresponsive properties is highly significant from practical point of view. It is well known that the tacticity of the resultant polyethers can be affected by the employed polymerization catalyst (or initiator), even when a racemic epoxide monomer is used.\textsuperscript{2} Meanwhile, our present results demonstrated that a polyether with the targeted thermoresponsive property can be unambiguously obtained regardless of the polymerization catalyst (or initiator). This is in sharp contrast to the bulk properties of the polyethers. In fact, a number of previous studies reported a significant difference in the polymer properties, such as melting point, glass transition temperature, and crystallinity, between the atactic and stereoregular polyethers. In addition, as shown in Table S3 and Figure S19, the atactic and isotactic poly(MeGE)s, poly(EtGE)s, and poly(MeEOGE)s exhibited a difference in the crystallization ability; the atactic ones did not show any evidence of crystallization and melting by the DSC measurement, while the isotactic ones showed both recrystallization and melting transitions during the second heating process.
