Calculation methods

Hardware. The hardware used for molecular modeling was the “Sun Hybrid System” based at the center for High Performance Computing in Cape Town, South Africa.

Software. The computational result in this study was calculated using the DMol3 density functional theory (DFT) code \(^1\text{ - }^3\) as implemented in Accelrys Materials Studio (Version 2016). The nonlocal generalized gradient approximation (GGA) exchange–correlation functional was employed in all geometry optimizations, viz., the PW91 functional of Perdew and Wang\(^4\). An all-electron polarized split valence basis set, termed double numeric polarized (DNP), was used. All
geometry optimizations employed highly efficient delocalized internal coordinates\textsuperscript{5}. The tolerance for convergence of the self-consistent field density was set to $1 \times 10^{-5}$ hartrees, while the tolerance for energy convergence was set to $1 \times 10^{-6}$ hartrees. Additional convergence criteria included the tolerance for converged gradient (0.002 hartree Å\textsuperscript{-1}) and the tolerance for converged atom displacement (0.005 Å). The thermal smearing option in Materials Studio makes use of a fractional electron occupancy scheme at the Fermi level according to a finite-temperature Fermi function\textsuperscript{6}.

In all cases optimized geometries were subjected to full frequency analyses at the same GGA/PW91/DNP level of theory to verify the nature of the stationary points. Equilibrium geometry was characterized by the absence of imaginary frequencies. The reported relative Gibbs free energies refer to Gibbs free energy corrections to the total electronic energies at 298.15 K and 1 atm.

The preparation of liquid crystal (LC) cells
The transparency of the LC cell

UV/vis transmission spectroscopic measurements were employed to characterized the transparency of films. The UV-vis transmittance spectroscopies of fresh P7 and annealed P7 films in the range of 300-800 nm are shown in Figure S14a. The LC-aligning films were first subjected to annealing treatment before being vertically irradiated with LPL (365 nm, 5.0 J cm\(^{-2}\) dose at room temperature). The combination of thermal annealing and LPL irradiation of LC alignment films generated LC cells. The 5CB LC cell with the LC alignment layers prepared through sequence-controlled polymerization is seen in Figure S14b. From the photograph, the transparency of this LC cell can be easily seen. This good transparency is very conducive to application in LC displays.
