Experimental details

Electrolyte preparation
The procedures used to prepare the electrolytes, AlCl$_3$–NaCl–KCl (61-26-13 mol%) and AlCl$_3$–[C$_2$ mim]Cl (60-40 mol%), were the same as those reported by Hussey et al.$^{1,2}$ Anhydrous AlCl$_3$ (either Nippon Light Metal Company, specially-manufactured ultra-high purity grade, or Fluka, Fe free) was used as received. Anhydrous NaCl (Wako Pure Chemical Industries, Ltd.) and anhydrous KCl (Wako Pure Chemical Industries, Ltd.) were used after vacuum drying at 473 K. 1-Ethyl-3-methylimidazolium chloride [C$_2$ mim]Cl (Merck) was purified according to a previous report.$^2$ For AlCl$_3$–NaCl–KCl, the salts were mixed and then fused at 423 K. The melt was further purified by leaving small pieces of pure Al wire in the reagent bottle for one week at 423 K. For AlCl$_3$–[C$_2$ mim]Cl, AlCl$_3$ was slowly added to [C$_2$ mim]Cl to prevent thermal decomposition of the [C$_2$ mim]$^+$ cations. The resulting Lewis acidic IL was purified by a constant current electrolysis between the two Al electrodes for three days under agitation at room temperature. All preparation processes were conducted in an Ar-filled glovebox (Vacuum Atmospheres Co., NEXUS II system) with O$_2$ and H$_2$O < 1 ppm.

Electrochemical measurements
All electrochemical experiments were conducted in a two-electrode cell assembled in an Ar-filled glovebox. Measurements were carried out with a potentiostat/galvanostat (Princeton Applied Research, VersaSTAT 4), as described previously. Prior to cell assembly, all components were vacuum dried at 373 K for 24 h to remove residual water. Grafoil® (GrafTech Co.) electrodes were prepared without the use of any binder, solvent, or conductive additive in order to ensure that the measured electrochemical characteristics were fully attributed only to the cathode itself. The loading per electrode area is approximately 15 mg cm$^{-2}$. Aluminum foil (99.999% purity) served as both the reference and counter electrodes. Two sheets of glass fiber (Whatman, GF/A) soaked in the electrolyte were used as the separator. To prevent any unexpected chemical reactions derived from the Lewis acidic electrolyte, a glass container and a molybdenum plate (99.95% purity) current collector were used in the cathode assembly. The set-up is schematically illustrated in Fig. S2. Electrochemical
impedance spectroscopy (EIS) measurements were carried out over a frequency range from 200 kHz to 5 mHz with an AC perturbation amplitude of 10 mV.

Characterization

The ionic conductivity of the two electrolytes was measured with a conductivity meter (S230 SevenCompact, Mettler Toledo) paired with an InLab 751 probe. The electrolytes were thermally equilibrated at each temperature for at least 30 min prior to measurement. X-ray diffraction (XRD) data were collected on a Rigaku Ultima IV diffractometer with Cu Kα radiation at room temperature. The measurements were performed at 40 kV and 40 mA with a step size of 0.01°. For the ex situ XRD study, Grafoil® electrodes were prepared in the cells by applying a constant current of 100 mA g⁻¹ for a fixed period, followed by a constant potential charging to complete the anion intercalation. The electrodes recovered from the cells were instantly placed in an air-tight sample holder. Afterwards, the electrodes were immediately removed from the glovebox for XRD measurements. Charged electrodes prepared in AlCl₃–[C₂mim]Cl were not rinsed with a solvent before XRD measurements, while those prepared in AlCl₃–NaCl–KCl were rinsed with AlCl₃–[C₂mim]Cl at 393 K, with an awareness that the electrolyte removal process might alter the electrode chemistry,³⁴ otherwise no XRD signals from Grafoil® could be obtained. The molar concentration of chloroaluminate ILs are calculated based on the method as reported.⁵⁶ Because the equilibrium constant for the autosolvolysis reaction (2[AlCl₄]⁻ ⇌ [Al₂Cl₇]⁻ + Cl⁻) is quite small,⁷ the concentration of Cl⁻ is vanishing small in Lewis acidic ILs. The total concentration of [AlCl₄]⁻ and [Al₂Cl₇]⁻ in the ILs is therefore equal to the total concentration of the cationic species and can be readily evaluated. The weight of the binary RTIL containing one mole of cation is given by⁵

\[
M = M_C + 133.34N_{\text{AlCl}_3}/(1 - N_{\text{AlCl}_3})
\]

where \(M_C\) is the molecular weight of the 1-ethyl-3-methylimidazolium chloride, \(N_{\text{AlCl}_3}\) represents the apparent mole fraction of AlCl₃. The bulk concentration of anionic species is then
\[ C_{\text{Anion}}^+ = C_{\text{Cation}}^+ = 10^3 \rho / M \]

where \( \rho \) is the density of the ILs. The concentration of the ternary inorganic IL electrolyte can be derived using the same approach, except that \( M_C \) must be apportioned between the two alkali metal chloride salts. The density information for the calculation can be found in the previous reports by Fannin et al.\textsuperscript{5} and Midorikawa.\textsuperscript{8} The molar concentration obtained for 60-40 mol\% \( \text{AlCl}_3-\text{[C}_2\text{mim}]\text{Cl} \) is 3.89 M at 298 K, whereas for 60-30-10 mol\% \( \text{AlCl}_3-\text{NaCl–KCl} \), it is 6.56 M at 423 K.
