2-[(6-mercaptohexyl)oxy]methyl-12-crown-4 (3) and 2-[(6-mercaptohexyl)oxy]methyl-15-crown-5 (4) were synthesized as reported previously (S. Flink et al., *J. Am. Chem. Soc.* 1998, 120, 4652).

**Construction of nanotubes by binary self-assembly**

The mixtures of 1(2) (2.1 g, 5 mmol) and 2(2) (3.0 g, 5 mmol), 1(6) (2.2 g, 4.1 mmol) and 2(6) (3.0 g, 4.1 mmol), 1(10) (2.2 g, 2.6 mmol) and 2(10) (2.8 g, 2.6 mmol), were dispersed in pure water (100 ml) under reflux conditions. The resultant hot solutions were gradually cooled to room temperature.

**Preparation of gold seed particles**

According to a previously reported method (B. D. Busbee et al., *Adv. Mater.* 2003, 15, 414.), an aqueous solution (0.5 ml) of 0.01 M HAuCl₄ and an aqueous solution (0.5 ml) of 0.01 M sodium citrate were mixed in pure water (18 ml). An aqueous solution (0.5 ml) of 0.1 M NaBH₄ was added into the mixtures. The obtained gold seed particles were purified by centrifugation and decantation with pure water. The size of the obtained gold seed particles was estimated to be 3.5 nm by TEM observation and dynamic light scattering measurement (data not shown).

**Construction of GNRs by using NT-LC templates**

The aqueous dispersion (1 ml) of the gold seeds ([Au] = 0.26 mM) was mixed with the NT-LC templates (100 ml) composed of 1(n) and 2(n) ([1(2)] = [2(2)] = 50 mM, [1(6)] = [2(6)] = 41 mM, [1(10)] = [2(10)] = 26 mM). An aqueous solution (2.5 ml) of 0.01 M HAuCl₄ and then an aqueous solution (0.5 ml) of 0.1 M ascorbic acid were added into the resultant mixtures. After standing for 12 h, an aqueous solution (2.5 ml) of 100 mM the thiol-crown ether compounds 3 or 4 was poured to the GNRs grew on the NT-LC template. Near infrared irradiation (Nd-YAG laser, Wavelength: 1064 nm, Pulse width: 7 ns, Frequency: 20 Hz, Power: 0.7 W) was performed to release the GNRs functionalized with 3 or 4 from the NT-LC template. The supernatant containing the GNRs was separated from the nanotube aggregates as the precipitates, and was purified by centrifugation and decantation with pure water.

Fig. S3 (Left) Infrared spectra for the amide-I (green), amide-II (blue), CH$_2$ scissoring (red) bands of the nanotubes. The lower wavenumber of the amide-I band and the higher wavenumber of the amide-II band indicated the stronger intermolecular hydrogen bonds among 1(n) and 2(n). The single sharp peak of the CH$_2$ scissoring band indicated that the lateral chain packing (subcell structure) of the oligomethylene spacer of 1(n) and 2(n) has a triclinic parallel (T$\parallel$) type structure. (Right) powder X-ray diffraction patterns of the nanotubes. The three peaks in the wide angle region support the subcell structure.
