1. General information

All the obtained products were characterized by melting points (m.p), $^1$H-NMR, $^{13}$C-NMR and infrared spectra (IR). Melting points were measured on an Electrothemal SGW-X4 microscopy digital melting point apparatus and are uncorrected; IR spectra were recorded on a FTIR2000 spectrometer; $^1$H-NMR and $^{13}$C-NMR spectra were obtained on Bruker-400 and referenced to 7.26 ppm for chloroform solvent with TMS as internal standard (0 ppm). Chemical shifts were reported in parts per million (ppm, δ) downfield from tetramethylsilane. Proton coupling patterns are described as singlet (s), doublet (d), triplet (t), multiplet (m); TLC was performed using commercially prepared 100-400 mesh silica gel plates (GF254), and visualization effected at 254 nm; High performance liquid chromatography (HPLC) analyses were performed on an Agilent Technologies 1260 Infinity II instrument equipped with a quaternary pump, using Daicel Chiralcel IA Columns (250 mmL × 4.6 mm φ). UV absorption was monitored at 254 nm. Unless otherwise stated, all the reagents were purchased from commercial sources (Energy Chemic, J&K Chemic, TCI, Fluka, Acros, SCRC), used without further purification; Cyclic voltammetry (CV) analysis was performed on Ingsens IGS-1030 electrochemical workstation (Ingsens Instruments (Guangzhou) Co., Ltd., China) with a conventional three-electrode cell, using a platinum electrode (d = 2 mm) as working electrode, a Pt wire as counter electrode and saturated calomel electrode (SCE) as a reference electrode. Cyclic voltammograms were recorded at 50 mV/s scan rate.

3. Optimization of the reaction conditions

To examine the feasibility of the above idea, we initiated our study by choosing the reaction of tetrahydroquinoline 1a and aniline 2a as a model system to evaluate different reaction parameters. First, the reaction charged with O₂ balloon in toluene was performed at 60 °C for 24 h in the presence of 15 mol % CuCl and 1.5 equivalents of pyridine. However, it failed to give any desired product 3aa, and only quinoline 1a’ and azo compound 2a-1 were observed (Table 1, entry 1). Interestingly, addition of 15 mol % of TEMPO into the reaction led to generate 3aa in 32% GC yield along with a certain amount of 2-aminodihydroquinoline 3a-1 (entry 2). Then, upon addition of TEMPO, a series of copper salts (entries 2-8) and solvents (entries 9-12) were screened, and the combination of CuCl and apolar p-xylene showed to be the best choice (entry 9). Further,
an increase of reaction temperature to 80 °C or the absence of copper salt failed to afford product 3aa (entry 13), indicating that the copper catalyst and a low temperature are two key factors for product formation. Similarly, the change of pyridine to other basic additives resulted in no product formation or poor yield (entry 14). Gratifyingly, a gradient change on temperature significantly improved the yield (entry 15, 81%). Thus, the optimal conditions are as indicated in entry 15.

[^a]: Reaction conditions: unless otherwise stated, the reaction in solvent (1.5 mL) was performed with 1a (0.3 mmol), 2a (0.3 mmol), cat. (15 mol %), TEMPO (15 mol %), additive (1.5 equiv) at 60 °C for 24 h charged with a O₂ balloon.[^b]: GC yield.[^c]: Without addition of TEMPO.[^d]: 80 °C or the absence of CuCl.[^e]: Yield are with respect to use of (Et)₃N, DBU, K₂CO₃ and t-BuOK as the additives, respectively.[^f]: 45 °C for 10 h then at 95 °C for 12 h.

4. Typical procedure for synthesis of 2- aminoquinolines
The mixture of 1,2,3,4-tetrahydroquinolines (0.3 mmol), amine (0.3 mmol), pyridine (0.45 mmol), TEMPO (0.045 mmol) and CuCl (0.045 mmol) in p-xylene (1.5 mL) was stirred at 45 °C for 10 hours under 1 atm of O₂ atmosphere (using O₂ balloon) and then heat to 95°C for 12 hours. After cooling down to room temperature, the resulting mixture was extracting with ethyl acetate, washed with purified water, and then concentrated by removing the solvent under vacuum. Finally, the residue was purified by preparative TLC on silica, eluting with petroleum ether (60-90 °C) : ethyl acetate (15:1~1:2) to give 2-aminoquinolines.

5. Representative time course for the model reaction

The model reactions with (a) or without (b) TEMPO were performed at 45 °C for 10 h, respectively. The reactions were carried out at different reaction times and the reaction mixture was analyzed by GC using hexadecane as the internal standard.

As shown in Figure S1a, THQ 1a was rapidly consumed to give the dihydroquinolines (imine 1a-1 and enamine 1a-2) within 1.5 h. Then, the concentrations of aniline 2a and dihydroquinolines gradually decreased, and 2-aminodihydroquinoline 3a-1 accumulated to a constant yield around 10 h. Then, 3a-1 could be fully transformed into product 2-phenylaminoquinoline (3aa) by prolonging the reaction for another 20 h at elevated temperature (95 °C, see SI, eq 2). The results indicate that dihydroquinolines and 3a-1 are the successive intermediates for the formation of 3aa. In comparison, the reaction without TEMPO (Figure S1b) leads to slow generation of dihydroquinolines, only small portion of aniline 2a was slowly converted into 3a-1 and 3aa, and quinoline 1a’ was produced as a major product. Clearly, the addition of TEMPO makes the first dehydrogenation of THQ a kinetically favorable process, the high concentration of dihydroquinolines favors the addition of amino nucleophiles, even including weak amide and sulfamide nucleophiles, and the conversion of 3a-1 to 3aa is a thermodynamically driven step.

6. The control experiments

To gain insight into the reaction mechanism, several verification experiments were performed. First, the model reaction was performed under the standard conditions but at 45 °C for 4 h and 2-Aminoimine intermediate 3a-1 was isolated and confirmed by GC–MS and NMR analyses (eq 1), and then, 3a-1 could be fully transformed into product 2-phenylaminoquinoline (3aa) by prolonging the reaction for another 12 h at elevated temperature (95 °C, eq 2), which indicated that 2-Aminoimine intermediate 3a-1 was the successive intermediate for the formation of 3aa. Noteworthy, the model reaction or 2-aminodihydroquinoline 3a-1 under the standard conditions by treating with excess BHT (butylated hydroxytoluene) suppressed the formation of product 3aa, showing that the reaction involves radical pathways (See eq 3 and eq 4). Further, the reaction of 2a with imine 1a-1 or its tautomer (enamine 1a-2) under the standard conditions succeed to yield product 3aa (eq 5), showing that imine 1a-1 or its tautomer (enamine 1a-2) which generated from the first dehydrogenation of 1a are the crucial intermediate.

![Chemical structure and equation]

The mixture of 1,2,3,4-tetrahydroquinolines (0.3 mmol), pyridine (0.6 mmol), 15 mol % TEMPO and 15 mol % CuCl in p-xylene (1.5 mL) was stirred at 40 °C for 1.5 hours under 1 atm of O₂ atmosphere (using O₂ balloon). After cooling down to room temperature, the reaction mixture contained the mixture of enamine (B) and imine (C). Upon GC–MS analysis, the ratio of 1a-1 to 1a-2 is 6:1. Then, we continued adding aniline (0.3 mmol) to the reaction mixture at 45 °C for 10 hours then 95 °C for 12 hours. After cooling down to room temperature, the resulting mixture was extracting with ethyl acetate, washed with purified water, and then concentrated by removing the solvent under vacuum. Finally the residue was purified by preparative TLC on silica.
