Experimental section

Reagent and materials

NF-κB p50 was bought from Enzo Life Sciences (NY, U.S.A.). Methylene blue (MB), tris(2-carboxyethyl)phosphine hydrochloride (TCEP), ethylenediaminetetraacetic acid (EDTA), bovine serum albumin (BSA), human serum albumin (HSA) and human immunoglobulin G (IgG) were supplied by Sigma-Aldrich (St. Louis, MO, U.S.A.). Exonuclease III (Exo III) was obtained from New England Biolabs (Ipswich, USA). Iron (III) chloride hexahydrate (FeCl₃·6H₂O), terephthalic acid (BDC), potassium platinocloride (K₂PtCl₄), nickel (II) chloride hexahydrate (NiCl₂·6H₂O), sodium borohyride (NaBH₄), acetic acid (HAc) and sodium acetate (NaAc) were received from Aladdin Chemicals Co. Ltd. N,N-dimethylformamide (DMF) and other chemical reagents are analytical reagent (A.R.) grade.

The buffers involved in this work were prepared as follows: Phosphate buffered solution (PBS, 0.1 M, pH 7.4) containing KH₂PO₄ (0.1 M), Na₂HPO₄ (0.1 M) and KCl (0.1 M) was used as the electrolyte solution. HAc-NaAc (0.1 M, pH 5.5) was served as working buffer solution. 5 mM [Fe(CN)₆]⁴⁻/₃⁻ solution containing 0.1 M KCl was employed as a redox probe for electrochemical characterization. DNA hybridization buffer (HB, pH 7.4) containing 10 mM Tris-HCl, 1.0 M NaCl and 1.0 mM EDTA was used for preparing the oligonucleotide solutions. Probe immobilization buffer (IB, pH 7.4) contained 10 mM tris(2-carboxyethyl)phosphine hydrochloride (TCEP), 10 mM Tris-HCl, 1.0 mM ethylenediaminetetraacetic acid (EDTA) and 0.1 M NaCl. Ultrapure water was used in all experiments. All
oligonucleotides (including MB-labeled DNA) were synthesized by Shanghai Sangon Biotechnology Co., Ltd. (Shanghai, China) and were dissolved in Tris-HCl buffer (10 mM, pH 7.4) to get the stock solution. The sequences were listed as follows (The bold regions denote the specific recognition sequences of NF-κB p50):

Signal probe (SP): 5′-MB-(CH$_2$)$_6$-ACCCTCTGTAGGTTGTATAGAAAACAGAGGGT-(CH$_2$)$_6$-SH-3′

Assistant probe (AP): 5′-AACCTTTTCTATACAACCTACTACCTCA-3′

ON1: 5′-TGAGGTAGTAGGTTGTATAGAAAAGGTTAAGGTTT$_2$ACT$_3$C$_2$ATCT-3′

ON2: 5′-AGATG$_2$$_2$$_2$GTC$_3$AACCTTTAACCTTTTCTATACAACCTACTACCTCA-3′

**Apparatus**

Electrochemical measurements, including cyclic voltammetry (CV), electrochemical impedance spectroscopy (EIS) and square wave voltammetry (SWV) were implemented by a CHI660E electrochemical workstation (Chenhua Instruments Co., Shanghai, China). A three-electrode system including a modified glassy carbon electrode (GCE, $\phi = 4$ mm) was used as working electrode, a saturated calomel electrode (SCE) acted as the reference electrode and a Pt wire served as auxiliary electrode. The morphologies, structural and composition analysis of different materials were characterized by scanning electron microscopy (SEM, Carl Zeiss Microscopy GmbH., Germany), powder X-ray diffraction (PXRD, Bruker D8), X-ray photoelectron spectra (XPS, Perkin-Elmer) and inductively coupled plasma atomic emission spectroscopy (ICP-AES, 725-ES).

**Synthesis of MIL-101 (Fe) and PtNi@MIL-101**
MIL-101 (Fe) was synthesized according to a previous report [1] with some modification. Typically, 0.268 g FeCl$_3$·6H$_2$O and 0.082 g BDC were dissolved in 8.0 mL DMF with ultrasonic dispersion. Then, the homogeneous solution was transferred to a 10 mL Teflon-liner autoclave and heated at 105 °C for 20 h. After cooling down to room temperature, the yellow products were isolated by centrifugation and washed with DMF and ethanol. Finally, the product was dried overnight at 60 °C for further use.

PtNi@MIL-101 was prepared via a facile impregnation method. Briefly, MIL-101 (Fe) (25 mg), K$_2$PtCl$_4$ (10.38 mg), NiCl$_2$·6H$_2$O (5.94 mg) were suspended in H$_2$O (5 mL) under ultrasonication. After that, the above suspension was vigorously stirred for 9 h to impregnate the Pt$^{2+}$ and Ni$^{2+}$ precursors into the pores of the MIL-101. Subsequently, 1 mL freshly prepared 0.6 M aqueous NaBH$_4$ solution was quickly added the above solution while vigorous stirring, resulting in the generation a celadon suspension. After reaction for 20 min, the synthesized samples were collected by centrifuging and dried at vacuum freeze-drying.

**Fabrication of the electrochemical biosensor interface**

Before the fabrication of biosensor, 50 μL SP (2 μM, 1 mM TCEP) were mixed with 50 μL AP (2 μM, HB). Then, the mixture was heated to 95 °C for 5 min and cooled down to room temperature to obtain the duplex probe (SP-AP, 1 μM). The sensor fabrication process is as follows. Firstly, the GCE was polished with 0.3, and 0.05 μm alumina powder, respectively, followed by sonication with ultrapure water, and dried in the air to obtain a mirror-like surface. After that, 15 μL the prepared
PtNi@MIL-101 was assembled onto the cleaned GCE over 6 h at room temperature.

Next, 10 μL as-prepared duplex probe (SP-AP, 1 μM) was dropped onto the electrode and incubated at 4 °C overnight. Lastly, the modified electrodes were treated with BSA (0.25%) for 30 min at room temperature to prevent any non-specific adsorption. Followed by each modification, the electrodes were washed with ultrapure water to avoid physical adsorption. Finally, the prepared electrodes (BSA/SP-AP/PtNi@MIL-101/GCE) were stored at 4 °C when not in use.

**Electrochemical NF-κB p50 detection**

NF-κB p50 detection procedure: Initially, the complete complementary DNA duplex (ON1/ON2, 1 μM) containing a NF-κB p50 recognition site was prepared by mixing 50 μL ON1 (2 μM, HB) and 50 μL ON2 (2 μM, HB). Then the mixed sequences were heated to 95 °C for 5 min, cooled down to room temperature and distributed to various microcentrifuge tubes. For the assay of NF-κB p50, various concentrations of NF-κB p50 were added into the mixture to incubate at room temperature for 40 min to allow NF-κB p50 protein binding with its recognition DNA sequences. After that, the digestion reaction was started at 37 °C for 40 min with the addition of 1 μL Exo III (2 U) and 10 μL buffer. Finally, the reacted solution was dropped onto the modified electrode and further incubated at 37 °C for about 1 h to actuate the signal amplification procedure before the electrochemical test.

All measurements were performed with a CHI660E electrochemical workstation.

SWV experiment was carried out in 0.1 M HAc-NaAc buffer (pH 5.5) at a potential range from -0.5 V to 0.1 V (vs. SCE). The fabrication process of the electrode was
characterized by CV and EIS in 0.1 M PBS (pH 7.4) containing 5 mM [Fe(CN)₆]⁴⁻/³⁻ as redox probe. CV experiment was carried out with a potential window from -0.2 V to 0.6 V at a scan rate of 0.1 V s⁻¹. EIS measurement was determined at a frequency window from 0.01 Hz to 100 KHz with the 5 mV alternative voltage.

**Design of electrochemical biosensor for NF-κB p50 assay**

A structure-switching electrochemical method was designed, and the two-part formed mechanism of this assay was outlined in Scheme 1. The partially hybridized probe complex (SP-AP) is first self-assembled on the electrode via thiol-PtNi alloy affinity, which maintains the signal probe with a rigid linear structure, keeping the electroactive reporter MB far away from the electrode surface. In the signal converter part, ON1 and ON2 are complete hybridized dsDNA, which contained the binding sequence (red regions of ON1 and ON2) of NF-κB p50. In the presence of NF-κB p50 and Exo III, ON3 attached with the Exo III’s digestion product NF-κB p50/dsDNA complex produced due to the protection of NF-κB p50 against the continually digestion of the recognition sites by Exo III. In this way, NF-κB p50 signal translates into the ON3. Then, ON3 was introduced into the reaction system and further hybridize with AP, which results in SP return to hairpin-like conformation and thus brings MB in proximity to the electrode surface. More importantly, ON3/AP with blunt 3′ terminus would trigger the digestion of Exo III and thus released ON3, which realizes the Exo III-assisted cycling amplification. As a result, a large amount of MB bring in proximity to the electrode surface and can further be catalyzed by PtNi@MIL-101, realizing an highly efficient 1:N target-responsive strategy.
Eventually, a significantly amplified current is obtained.

Results and discussion

PXRD measurement

The structural characterization of the PtNi@MIL-101 above is confirmed by PXRD measurements. As displayed in Fig. S1, the experimental diffractogram of MIL-101 (Fe) is in good agreement with the simulated one of MIL-101 (Fe), the synthetic PtNi@MIL-101 is completely overlapped with that of MIL-101 (Fe), demonstrating that the sample of MIL-101 (Fe) has high purity and no crystallinity loss after the formation of PtNi@MIL-101.

Characterization of the electrochemical biosensor

CV and EIS measurements were used to investigate the modification process of prepared electrode in 5.0 mM [Fe(CN)₆]⁴⁻/³⁻ solution, and the results are presented in Fig. S2A and B. As we can see from Fig. S2A, the bare GCE exhibits a couple of
apparent quasi-reversible redox peak of \([\text{Fe(CN)}_6]^{4-/3-}\) (curve a). After PtNi@MIL-101 was assembled onto the cleaned GCE, a larger peak current than that of bare GCE appears (curve b), which can be attributed to the satisfactory electro-conductivity of PtNi alloy nanoclusters. Then, the following introduction of non-electroactive SP-AP onto the resulting electrode surface caused the decrease of the peak current (curve c). Subsequently, a dramatic dropped peak current can be obtained when the electrode surface was blocked with BSA (curve d). After modification with NF-κB p50 reacted solution (the mixture containing ON1/ON2, NF-κB p50 and Exo III), an increased CV response is obtained (curve e), which may be originated from that the ON3 can trigger a strand displacement reaction by forming AP/ON3 duplex that is then released into the bulk solution, which led to the AP away from the electrode surface. Furthermore, EIS of every modification step is displayed in Fig. S2B, the diameter of the semicircle can manifest electron transfer resistance \(R_{et}\) of the electrode surface. It is found that the bare GCE exhibits a small semicircle (curve a). After modification of PtNi@MIL-101 on the GCE, we can see that the \(R_{et}\) value is gradually decreased (curve b), owing to the good conductivity of PtNi alloy nanoclusters. However, when the negatively charged SP-AP duplex and BSA were successively immobilized on the electrode surface, the diameter increases in order (curve c and d), because DNA sequences and protein as electron transfer blocking layer can retard the electron transfer. In the end, there is an apparent increase of the diameter (curve e) after incubation of NF-κB p50 reacted solution, which is attributed to the fact that the AP is taken away from the electrode surface. All the results obtained reveal the successful fabrication of the
constructed sensor.

**Fig. S2.** CV (A) and EIS (B) responses of the fabricated procedures for the biosensor performed in PBS (pH 7.4) containing 5 mM [Fe(CN)₆]⁴⁻/₃⁻ as a redox probe: (a) bare GCE, (b) PtNi@MIL-101/GCE, (c) SP-AP/PtNi@MIL-101/GCE, (d) BSA/SP-AP/PtNi@MIL-101/GCE, and (e) after being incubated with NF-κB p50 reacted solution.

**Optimization of biosensor preparation conditions**

To obtain the best analytical performance for NF-κB p50 detection, several factors were taken into consideration, including the concentration of SP, the concentration and incubation time of Exo III. As shown in Fig. S3A, the concentration of SP is an important parameter in response of the prepared biosensor, SWV peak current gradually increased as the concentration of SP elevated from 0.1 to 1.0 μM, and then decreased after over 1 μM. The reason could be that higher density of SP would induce steric hindrances and thus prevent SP from forming the hairpin structure on the electrode surface. Hence, the concentration of SP at 1.0 μM was optimized. Fig. S3B depicts the effect of the concentration of Exo III, it is found that the peak current gradually exhibits a positive correlation with the concentration of Exo III, and reaches
its plateau when the concentration was 2.0 U μL\(^{-1}\). Thus, 2.0 U μL\(^{-1}\) of Exo III is used as the optimal concentration. In addition, the incubation time of Exo III also plays an important role in constructed biosensor. From Fig. S3C, SWV response increases clearly with the increasing incubation time of Exo III from 20 to 60 min, and remains unchanged after 60 min. Therefore, the optimal incubation time of Exo III is 60 min.
